## New Foreword

On October 1, 2001 Axiom was withdrawn from the market and ended life as a commercial product. On September 3, 2002 Axiom was released under the Modified BSD license, including this document. On August 27, 2003 Axiom was released as free and open source software available for download from the Free Software Foundation's website, Savannah.

Work on Axiom has had the generous support of the Center for Algorithms and Interactive Scientific Computation (CAISS) at City College of New York. Special thanks go to Dr. Gilbert Baumslag for his support of the long term goal.

The online version of this documentation is roughly 1000 pages. In order to make printed versions we've broken it up into three volumes. The first volume is tutorial in nature. The second volume is for programmers. The third volume is reference material. We've also added a fourth volume for developers. All of these changes represent an experiment in print-on-demand delivery of documentation. Time will tell whether the experiment succeeded.

Axiom has been in existence for over thirty years. It is estimated to contain about three hundred man-years of research and has, as of September 3, 2003, 143 people listed in the credits. All of these people have contributed directly or indirectly to making Axiom available. Axiom is being passed to the next generation. I'm looking forward to future milestones.

With that in mind I've introduced the theme of the "30 year horizon". We must invent the tools that support the Computational Mathematician working 30 years from now. How will research be done when every bit of mathematical knowledge is online and instantly available? What happens when we scale Axiom by a factor of 100, giving us 1.1 million domains? How can we integrate theory with code? How will we integrate theorems and proofs of the mathematics with space-time complexity proofs and running code? What visualization tools are needed? How do we support the conceptual structures and semantics of mathematics in effective ways? How do we support results from the sciences? How do we teach the next generation to be effective Computational Mathematicians?

The "30 year horizon" is much nearer than it appears.

Tim Daly  
CAISS, City College of New York  
November 10, 2003 ((iHy))

# Chapter 1

## Chapter Overview

This book contains the domains in Axiom, in alphabetical order.

Each domain has an associated 'dotpic' chunk which only lists the domains, categories, and packages that are in the layer immediately below in the build order. For the full list see the algebra Makefile where this information is maintained.

Each domain is preceded by a picture. The picture indicates several things. The colors indicate whether the name refers to a category, domain, or package. An ellipse means that the name refers to something in the bootstrap set. Thus,

++ Description:
++ This package factors multivariate polynomials over the
++ domain of \spadtype{AlgebraicNumber} by allowing the user
++ to specify a list of algebraic numbers generating the particular
++ extension to factor over.

```

```

public ==> with

leftRank: A -> NonNegativeInteger
++ leftRank(x) determines the number of linearly independent elements
++ in \spad{x*b1},...,\spad{x*bn},
++ where \spad{b=[b1,...,bn]} is a basis.
rightRank: A -> NonNegativeInteger
++ rightRank(x) determines the number of linearly independent elements
++ in \spad{b1*x},...,\spad{bn*x},
++ where \spad{b=[b1,...,bn]} is a basis.
doubleRank: A -> NonNegativeInteger
++ doubleRank(x) determines the number of linearly
++ independent elements
++ in \spad{b1*x},...,\spad{x*bn},
++ where \spad{b=[b1,...,bn]} is a basis.
weakBiRank: A -> NonNegativeInteger
++ weakBiRank(x) determines the number of
++ linearly independent elements
++ in the \spad{bi*x*bj}, \spad{i,j=1,...,n},
++ where \spad{b=[b1,...,bn]} is a basis.
biRank: A -> NonNegativeInteger
++ biRank(x) determines the number of linearly independent elements
++ in \spad{x}, \spad{x*bi}, \spad{bi*x}, \spad{bi*x*bj},
++ \spad{i,j=1,...,n},
++ where \spad{b=[b1,...,bn]} is a basis.
++ Note that if \spad{A} has a unit,
++ then doubleRank, weakBiRank, and biRank coincide.
basisOfCommutingElements: () -> List A
++ basisOfCommutingElements() returns a basis of the space of
++ all x of \spad{A} satisfying \spad{0 = commutator(x,a)} for all
++ \spad{a} in \spad{A}.
basisOfLeftAnnihilator: A -> List A
++ basisOfLeftAnnihilator(a) returns a basis of the space of
++ all x of \spad{A} satisfying \spad{0 = x*a}.
basisOfRightAnnihilator: A -> List A
++ basisOfRightAnnihilator(a) returns a basis of the space of
++ all x of \spad{A} satisfying \spad{0 = a*x}.
basisOfLeftNucleus: () -> List A
++ basisOfLeftNucleus() returns a basis of the space of
++ all x of \spad{A} satisfying \spad{0 = associator(x,a,b)}
++ for all \spad{a},b in \spad{A}.

```

```

basisOfRightNucleus: () -> List A
++ basisOfRightNucleus() returns a basis of the space of
++ all x of \spad{A} satisfying \spad{0 = associator(a,b,x)}
++ for all \spad{a},b in \spad{A}.
basisOfMiddleNucleus: () -> List A
++ basisOfMiddleNucleus() returns a basis of the space of
++ all x of \spad{A} satisfying \spad{0 = associator(a,x,b)}
++ for all \spad{a},b in \spad{A}.
basisOfNucleus: () -> List A
++ basisOfNucleus() returns a basis of the space of
++ all x of \spad{A} satisfying
++ \spad{associator(x,a,b) = associator(a,x,b) = associator(a,b,x) = 0}
++ for all \spad{a},b in \spad{A}.
basisOfCenter: () -> List A
++ basisOfCenter() returns a basis of the space of
++ all x of \spad{A} satisfying \spad{commutator(x,a) = 0} and
++ \spad{associator(x,a,b) = associator(a,x,b) = associator(a,b,x) = 0}
++ for all \spad{a},b in \spad{A}.
basisOfLeftNucloid:()-> List Matrix R
++ basisOfLeftNucloid() returns a basis of the space of
++ endomorphisms of \spad{A} as right module.
++ Note that left nucloid coincides with left nucleus
++ if \spad{A} has a unit.
basisOfRightNucloid:()-> List Matrix R
++ basisOfRightNucloid() returns a basis of the space of
++ endomorphisms of \spad{A} as left module.
++ Note that right nucloid coincides with right nucleus
++ if \spad{A} has a unit.
basisOfCentroid:()-> List Matrix R
++ basisOfCentroid() returns a basis of the centroid, i.e. the
++ endomorphism ring of \spad{A} considered as \spad{(A,A)}-bimodule.
radicalOfLeftTraceForm: () -> List A
++ radicalOfLeftTraceForm() returns basis for null space of
++ \spad{leftTraceMatrix()}, if the algebra is
++ associative, alternative or a Jordan algebra, then this
++ space equals the radical (maximal nil ideal) of the algebra.
if R has EuclideanDomain then
  basis : V A -> V A
  ++ basis(va) selects a basis from the elements of va.

## 2.10 package ALGFACT AlgFactor

### 2.10.1 AlgFactor (ALGFACT)

#### Exports:

doublyTransitive? factor split

— package ALGFACT AlgFactor —

```

)abbrev package ALGFACT AlgFactor
++ Author: Manuel Bronstein
++ Date Created: ???
++ Date Last Updated: ???
++ Description:
++ Factorization of univariate polynomials with coefficients in
++ \spadtype{AlgebraicNumber}.

AlgFactor(UP): Exports == Implementation where
  UP: UnivariatePolynomialCategory AlgebraicNumber

N ==> NonNegativeInteger
Z ==> Integer
Q ==> Fraction Integer
AN ==> AlgebraicNumber
K ==> Kernel AN
UPQ ==> SparseUnivariatePolynomial Q
SUP ==> SparseUnivariatePolynomial AN
FR ==> Factored UP

Exports ==> with
  factor: (UP, List AN) -> FR
    ++ factor(p, [a1,...,an]) returns a prime factorisation of p
    ++ over the field generated by its coefficients and a1,...,an.
  factor: UP -> FR
    ++ factor(p) returns a prime factorisation of p
    ++ over the field generated by its coefficients.

```

```

split : UP          -> FR
++ split(p) returns a prime factorisation of p
++ over its splitting field.
doublyTransitive?: UP -> Boolean
++ doublyTransitive?(p) is true if p is irreducible over
++ over the field K generated by its coefficients, and
++ if  $\text{\texttt{\$spad}\{p(X) / (X - a)\}}$  is irreducible over
++  $\text{\texttt{\$spad}\{K(a)\}}$  where  $\text{\texttt{\$spad}\{p(a) = 0\}}$ .

  measure:NumericalOptimizationProblem -> Measure
    ++ measure(prob) is a top level ANNA function for identifying the most
    ++ appropriate numerical routine from those in the routines table
    ++ provided for solving the numerical optimization problem defined by
    ++ \axiom{prob} by checking various attributes of the functions and
    ++ calculating a measure of compatibility of each routine to these
    ++ attributes.
    ++
    ++ It calls each \axiom{domain} of \axiom{category}
    ++ \axiomType{NumericalOptimizationCategory} in turn to calculate all
    ++ measures and returns the best i.e. the name of the most
    ++ appropriate domain and any other relevant information.

  measure:(NumericalOptimizationProblem,RT) -> Measure
    ++ measure(prob,R) is a top level ANNA function for identifying the most
    ++ appropriate numerical routine from those in the routines table
    ++ provided for solving the numerical optimization problem defined by
    ++ \axiom{prob} by checking various attributes of the functions and
    ++ calculating a measure of compatibility of each routine to these
    ++ attributes.
    ++
    ++ It calls each \axiom{domain} listed in \axiom{R} of \axiom{category}
    ++ \axiomType{NumericalOptimizationCategory} in turn to calculate all
    ++ measures and returns the best i.e. the name of the most
    ++ appropriate domain and any other relevant information.

  optimize:(NumericalOptimizationProblem,RT) -> Result
    ++ optimize(prob,routines) is a top level ANNA function to
    ++ minimize a function or a set of functions with any constraints
    ++ as defined within \axiom{prob}.
    ++
    ++ It iterates over the \axiom{domains} listed in \axiom{routines} of
    ++ \axiomType{NumericalOptimizationCategory}
    ++ to get the name and other relevant information of the best
    ++ \axiom{measure} and then optimize the function on that \axiom{domain}.

```

```

optimize:NumericalOptimizationProblem -> Result
++ optimize(prob) is a top level ANNA function to
++ minimize a function or a set of functions with any constraints
++ as defined within \axiom{prob}.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{NumericalOptimizationCategory}
++ to get the name and other relevant information of the best
++ \axiom{measure} and then optimize the function on that \axiom{domain}.

goodnessOfFit:NumericalOptimizationProblem -> Result
++ goodnessOfFit(prob) is a top level ANNA function to
++ check to goodness of fit of a least squares model
++ as defined within \axiom{prob}.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{NumericalOptimizationCategory}
++ to get the name and other relevant information of the best
++ \axiom{measure} and then optimize the function on that \axiom{domain}.
++ It then calls the numerical routine \axiomType{E04YCF} to get estimates
++ of the variance-covariance matrix of the regression coefficients of
++ the least-squares problem.
++
++ It thus returns both the results of the optimization and the
++ variance-covariance calculation.

optimize:(EF,LF,LOCF,LEF,LOCF) -> Result
++ optimize(f,start,lower,cons,upper) is a top level ANNA function to
++ minimize a function, \axiom{f}, of one or more variables with the
++ given constraints.
++
++ These constraints may be simple constraints on the variables
++ in which case \axiom{cons} would be an empty list and the bounds on
++ those variables defined in \axiom{lower} and \axiom{upper}, or a
++ mixture of simple, linear and non-linear constraints, where
++ \axiom{cons} contains the linear and non-linear constraints and
++ the bounds on these are added to \axiom{upper} and \axiom{lower}.
++
++ The parameter \axiom{start} is a list of the initial guesses of the
++ values of the variables.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{NumericalOptimizationCategory}
++ to get the name and other relevant information of the best
++ \axiom{measure} and then optimize the function on that \axiom{domain}.

optimize:(EF,LF,LOCF,LOCF) -> Result
++ optimize(f,start,lower,upper) is a top level ANNA function to
++ minimize a function, \axiom{f}, of one or more variables with
++ simple constraints. The bounds on

```

```

++ the variables are defined in \axiom{lower} and \axiom{upper}.
++
++ The parameter \axiom{start} is a list of the initial guesses of the
++ values of the variables.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{NumericalOptimizationCategory}
++ to get the name and other relevant information of the best
++ \axiom{measure} and then optimize the function on that \axiom{domain}.

optimize:(EF,LF) -> Result
++ optimize(f,start) is a top level ANNA function to
++ minimize a function, \axiom{f}, of one or more variables without
++ constraints.
++
++ The parameter \axiom{start} is a list of the initial guesses of the
++ values of the variables.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{NumericalOptimizationCategory}
++ to get the name and other relevant information of the best
++ \axiom{measure} and then optimize the function on that \axiom{domain}.

optimize:(LEF,LF) -> Result
++ optimize(lf,start) is a top level ANNA function to
++ minimize a set of functions, \axiom{lf}, of one or more variables
++ without constraints i.e. a least-squares problem.
++
++ The parameter \axiom{start} is a list of the initial guesses of the
++ values of the variables.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{NumericalOptimizationCategory}
++ to get the name and other relevant information of the best
++ \axiom{measure} and then optimize the function on that \axiom{domain}.

goodnessOfFit:(LEF,LF) -> Result
++ goodnessOfFit(lf,start) is a top level ANNA function to
++ check to goodness of fit of a least squares model i.e. the minimization
++ of a set of functions, \axiom{lf}, of one or more variables without
++ constraints.
++
++ The parameter \axiom{start} is a list of the initial guesses of the
++ values of the variables.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{NumericalOptimizationCategory}
++ to get the name and other relevant information of the best
++ \axiom{measure} and then optimize the function on that \axiom{domain}.
++ It then calls the numerical routine \axiomType{E04YCF} to get estimates

```

```

++ of the variance-covariance matrix of the regression coefficients of
++ the least-squares problem.
++
++ It thus returns both the results of the optimization and the
++ variance-covariance calculation.

++ goodnessOfFit(lf,start) is a top level function to iterate over
++ the \axiom{domains} of \axiomType{NumericalOptimizationCategory}
++ to get the name and other relevant information of the best
++ \axiom{measure} and then optimize the function on that \axiom{domain}.
++ It then checks the goodness of fit of the least squares model.

### 2.13. PACKAGE ODEPACK ANNAORDINARYDIFFERENTIAL EQUATION PACKAGE 71

```

++ solve(odeProblem) is a top level ANNA function to solve numerically a
++ system of ordinary differential equations i.e. equations for the
++ derivatives y[1]'.y[n]' defined in terms of x,y[1]..y[n], together
++ with starting values for x and y[1]..y[n] (called the initial
++ conditions), a final value of x, an accuracy requirement and any
++ intermediate points at which the result is required.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{OrdinaryDifferentialEquationsSolverCategory}
++ to get the name and other
++ relevant information of the the (domain of the) numerical
++ routine likely to be the most appropriate,
++ i.e. have the best \axiom{measure}.
++
++ The method used to perform the numerical
++ process will be one of the routines contained in the NAG numerical
++ Library. The function predicts the likely most effective routine
++ by checking various attributes of the system of ODE's and calculating
++ a measure of compatibility of each routine to these attributes.
++
++ It then calls the resulting 'best' routine.
solve:(NumericalODEProblem,RT) -> Result
++ solve(odeProblem,R) is a top level ANNA function to solve numerically a
++ system of ordinary differential equations i.e. equations for the
++ derivatives y[1]'.y[n]' defined in terms of x,y[1]..y[n], together
++ with starting values for x and y[1]..y[n] (called the initial
++ conditions), a final value of x, an accuracy requirement and any
++ intermediate points at which the result is required.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{OrdinaryDifferentialEquationsSolverCategory} contained in
++ the table of routines \axiom{R} to get the name and other
++ relevant information of the the (domain of the) numerical
++ routine likely to be the most appropriate,
++ i.e. have the best \axiom{measure}.
++
++ The method used to perform the numerical
++ process will be one of the routines contained in the NAG numerical
++ Library. The function predicts the likely most effective routine
++ by checking various attributes of the system of ODE's and calculating
++ a measure of compatibility of each routine to these attributes.
++
++ It then calls the resulting 'best' routine.
solve:(VEF,F,F,LF) -> Result
++ solve(f,xStart,xEnd,yInitial) is a top level ANNA function to solve
++ numerically a system of ordinary differential equations i.e. equations
++ for the derivatives y[1]'.y[n]' defined in terms of x,y[1]..y[n],
++ together with a starting value for x and y[1]..y[n] (called the initial
++ conditions) and a final value of x. A default value
++ is used for the accuracy requirement.

```

```

++
++ It iterates over the \axiom{domains} of
++ \axiomType{OrdinaryDifferentialEquationsSolverCategory} contained in
++ the table of routines \axiom{R} to get the name and other
++ relevant information of the the (domain of the) numerical
++ routine likely to be the most appropriate,

=====

ApplicationProgramInterface examples

=====

The ApplicationProgramInterface exposes Axiom internal functions which might be useful for understanding, debugging, or creating tools.

The getDomains function takes the name of a category and returns a set of domains which inherit from that category:

```
getDomains 'Collection
```

```
{AssociationList, Bits, CharacterClass, ComplexDoubleFloatVector, DataList,
 DoubleFloatVector, EqTable, FlexibleArray, GeneralPolynomialSet,
 GeneralSparseTable, GeneralTriangularSet, HashTable, IndexedBits,
 IndexedFlexibleArray, IndexedList, IndexedOneDimensionalArray,
```

```

IndexedString, IndexedVector, InnerTable, KeyedAccessFile, Library, List,
ListMultiDictionary, Multiset, NeitherSparseOrDensePowerSeries,
OneDimensionalArray, Point, PrimitiveArray, RegularChain,
RegularTriangularSet, Result, RoutinesTable, Set, SparseTable,
SquareFreeRegularTriangularSet, Stream, String, StringTable, Table,
U32Vector, Vector, WuWenTsunTriangularSet}

```

Type: Set Symbol

This can be used to form the set-difference of two categories:

```

difference(getDomains 'IndexedAggregate, getDomains 'Collection)

{DirectProduct, DirectProductMatrixModule, DirectProductModule,
HomogeneousDirectProduct, OrderedDirectProduct,
SplitHomogeneousDirectProduct}

```

Type: Set Symbol

The `credits` function prints a list of the people who have contributed to the development of Axiom. This is equivalent to the `)credits` command.

The `summary` function prints a short list of useful console commands.

The `getAncestors` function takes the name of a domain or category and returns a list of categories from which it inherits.

```

getAncestors 'IndexedAggregate

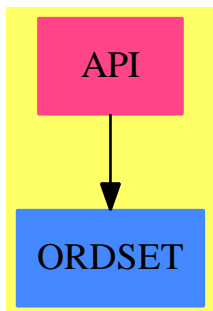

{Aggregate, BasicType, CoercibleTo, Eltable, EltableAggregate, Evaluable,
HomogeneousAggregate, InnerEvaluable, SetCategory, Type}

```

Type: Set(Symbol)

_____ package PMPRED AttachPredicates _____

)abbrev package PMPRED AttachPredicates
++ Predicates for pattern-matching
++ Author: Manuel Bronstein
++ Date Created: 21 Mar 1989
++ Date Last Updated: 23 May 1990
++ Keywords: pattern, matching.

```

```

++ Description:
++ Attaching predicates to symbols for pattern matching.

AttachPredicates(D:Type): Exports == Implementation where
  FE ==> Expression Integer

Exports ==> with
  suchThat: (Symbol, D -> Boolean) -> FE
    ++ suchThat(x, foo) attaches the predicate foo to x.
  suchThat: (Symbol, List(D -> Boolean)) -> FE
    ++ suchThat(x, [f1, f2, ..., fn]) attaches the predicate
    ++ f1 and f2 and ... and fn to x.

Implementation ==> add
  import FunctionSpaceAttachPredicates(Integer, FE, D)

  suchThat(p:Symbol, f:D -> Boolean)      == suchThat(p::FE, f)
  suchThat(p:Symbol, l:List(D -> Boolean)) == suchThat(p::FE, l)

## 2.21 package AXSERV AxiomServer

### 2.21.1 AxiomServer (AXSERV)

**Exports:**

```
multiServ  axServer  getDatabase
```

— package AXSERV AxiomServer —

```
)abbrev package AXSERV AxiomServer
++ Author: Arthur Ralfs, Timothy Daly, Alfredo Portes
++ Description:
++ This package provides a functions to support a web server for the
++ new Axiom Browser functions.

AxiomServer: public == private where

public == with

  axServer: (Integer, SExpression->Void) -> Void
  multiServ: SExpression -> Void
  getDatabase: (String,String) -> String

private == add

  getFile: (SExpression,String) -> Void
  getCommand: (SExpression,String) -> Void
  getDescription: String -> String
  getInterp: (SExpression,String) -> Void
  getLisp: (SExpression,String) -> Void
  getShow: (SExpression,String) -> Void
  lastStep: () -> String
  lastType: () -> String
  formatMessages: String -> String
  makeErrorPage: String -> String
  getSourceFile: (String,String,String) -> String
  makeDBPage: String -> String
  getContentType: String -> String
  readTheFile: SExpression -> String
  outputToSocket: (SExpression,String,String) -> Void

  getDatabase(constructor:String, key:String):String ==
    answer:=string GETDATABASE(INTERN$Lisp constructor,INTERN$Lisp key)$Lisp
--    WriteLine$Lisp concat ["getDatabase: ",constructor," ",key," ",answer]
    answer
```

---

The axServer function handles the socket connection on the given port. When it gets a input on the socket it calls the server function on the socket input.

— package AXSERV AxiomServer —

```
axServer(port:Integer,serverfunc:SExpression->Void):Void ==
  WriteLine$Lisp "listening on port 8085"
  s := SiSock(port,serverfunc)$Lisp
  -- To listen for just one connection and then close the socket
  -- uncomment i := 0.
  i:Integer := 1
  while (i > 0) repeat
    if not null?(SiListen(s)$Lisp)$SExpression then
      w := SiAccept(s)$Lisp
      serverfunc(w)
--      i := 0
```

The multiServ function parses the socket input. It expects either a GET or POST request. A GET request fetches a new page, calling “getFile”. A POST request starts with

- “command=” which expects axiom interpreter commands. When this is recognized we call the “getCommand” function.
- “lispcall=” which expects lisp interpreter input. When this is recognized we call the “getLisp” function.

— package AXSERV AxiomServer —

```
multiServ(s:SExpression):Void ==
--   WriteLine("multiServ begin")$Lisp
  headers:String := ""
  char:String
  -- read in the http headers
  while (char := _
    STRING(READ_-CHAR_-NO_-HANG(s,NIL$Lisp,'EOF)$Lisp)$Lisp) ^= "EOF"_
    repeat
      headers := concat [headers,char]
--   sayTeX$Lisp headers
  StringMatch("(^[^ ]*)", headers)$Lisp
  u:UniversalSegment(Integer)
  u := segment(MatchBeginning(1)$Lisp+1,_
    MatchEnd(1)$Lisp)$UniversalSegment(Integer)
  reqtype:String := headers.u
--   sayTeX$Lisp concat ["request type: ",reqtype]
  if reqtype = "GET" then
    StringMatch("GET ([^ ]*)",headers)$Lisp
    u:UniversalSegment(Integer)
```

```

    u := segment(MatchBeginning(1)$Lisp+1,_
                MatchEnd(1)$Lisp)$UniversalSegment(Integer)
    getFile(s,headers.u)
if reqtype = "POST" and StringMatch("command=(.*)$",headers)$Lisp > 0
then
    u:UniversalSegment(Integer)
    u := segment(MatchBeginning(1)$Lisp+1,_
                MatchEnd(1)$Lisp)$UniversalSegment(Integer)
    getCommand(s,headers.u)
if reqtype = "POST" and StringMatch("interpcall=(.*)$",headers)$Lisp > 0
then
    u:UniversalSegment(Integer)
    u := segment(MatchBeginning(1)$Lisp+1,_
                MatchEnd(1)$Lisp)$UniversalSegment(Integer)
    getInterp(s,headers.u)
if reqtype = "POST" and StringMatch("lispcall=(.*)$",headers)$Lisp > 0
then
    u:UniversalSegment(Integer)
    u := segment(MatchBeginning(1)$Lisp+1,_
                MatchEnd(1)$Lisp)$UniversalSegment(Integer)
    getLisp(s,headers.u)
if reqtype = "POST" and StringMatch("showcall=(.*)$",headers)$Lisp > 0
then
    u:UniversalSegment(Integer)
    u := segment(MatchBeginning(1)$Lisp+1,_
                MatchEnd(1)$Lisp)$UniversalSegment(Integer)
    getShow(s,headers.u)
--    WriteLine("multiServ end")$Lisp
--    WriteLine("")$Lisp

```

## getFile

Given a socket and the URL of the file we create an input stream that contains the file. If the filename contains a question mark then we need to parse the parameters and dynamically construct the file contents.

— package AXSERV AxiomServer —

```

getFile(s:SExpression,pathvar:String):Void ==
--    WriteLine("")$Lisp
    WriteLine$Lisp concat ["getFile: ",pathvar]
    params:=split(pathvar,char "?")
    if #params = 1
    then if not null? PATHNAME_-NAME(PATHNAME(pathvar)$Lisp)$Lisp
    then
        contentType:String := getContentType(pathvar)
        q:=Open(pathvar)$Lisp

```

```

if null? q
then
  q := MAKE_-STRING_-INPUT_-STREAM(_
      makeErrorPage("File doesn't exist"))$Lisp
else
  q:=MAKE_-STRING_-INPUT_-STREAM(_
      makeErrorPage("Problem with file path"))$Lisp
else
  q:=MAKE_-STRING_-INPUT_-STREAM(makeDBPage(pathvar))$Lisp
outputToSocket(s,readTheFile(q),contentType)

```

---

### makeErrorPage

— package AXSERV AxiomServer —

```

makeErrorPage(msg:String):String ==
  page:String:="<!DOCTYPE html PUBLIC "
  page:=page "_-//W3C//DTD XHTML 1.0 Strict//EN" "
  page:=page "_-http://www.w3.org/TR/xhtml1/DTD/xhtml1-strict.dtd-">"
  page:=page "<html xmlns=_-http://www.w3.org/1999/xhtml_">"
  page:=page "<head><title>Error</title></head><body>" msg "</body></html>"
--  WriteLine(page)$Lisp
  page

```

---

### getDescription

We need to fish around in the data structure to return the piece of documentation for the domain. We have to call the lisp version of GETDATABASE because the version above returns a string object. The string object is missing quotes and cannot be properly read. So we need to get the lisp object and work with it in native form first.

The doc string also contains spad markup which we need to replace with html.

— package AXSERV AxiomServer —

```

getDescription(dom:String):String ==
  d:=CADR(CADR(GETDATABASE(INTERN(dom)$Lisp,'DOCUMENTATION)$Lisp)$Lisp)$Lisp
  string d

```

---

**getSourceFile**

During build we construct a hash table that takes the chunk name as the key and returns the filename. We reconstruct the chunk name here and do a lookup for the source file.

— package AXSERV AxiomServer —

```

getSourceFile(constructorkind:String, _
              abbreviation:String, _
              dom:String):String ==
  sourcekey:="@<<" constructorkind " " abbreviation " " dom ">>"
--   WriteLine(sourcekey)$Lisp
  sourcefile:=lowerCase last split(getDatabase(dom,"SOURCEFILE"),char "/")
  sourcefile:=sourcefile ".pamphlet"

```

**makeDBPage**

— package AXSERV AxiomServer —

```

makeDBPage(pathvar:String):String ==
  params:List(String):=split(pathvar,char "?")
  for i in 1..#params repeat WriteLine$Lisp concat ["params: ",params.i]
  pathparts:List(String):=split(params.1,char "/")
  for i in 1..#pathparts repeat
    WriteLine$Lisp concat ["pathparts: ",pathparts.i]
  pagename:=last pathparts
  WriteLine$Lisp concat ["pagename: ",pagename]
  cmd:=first split(pagename,char ".")
  WriteLine$Lisp concat ["cmd: ",cmd]
  args:List(String):=split(params.2, char "&")
  for i in 1..#args repeat WriteLine$Lisp concat ["args: ",args.i]
  page:String:="<!DOCTYPE html PUBLIC "

page

```

---

### readTheFile

We have `q` which is a stream which contains the file. We read the file into a string-stream to get it all into one string. We return the string.

— package AXSERV AxiomServer —

```

readTheFile(q:SExpression):String ==
--   WriteLine("begin reading file")$Lisp
  r := MAKE_-STRING_-OUTPUT_-STREAM()$Lisp
  SiCopyStream(q,r)$Lisp
  filestream:String := GET_-OUTPUT_-STREAM_-STRING(r)$Lisp
  CLOSE(r)$Lisp
  CLOSE(q)$Lisp
--   WriteLine("end reading file")$Lisp
  filestream

```

---

### outputToSocket

We have “`s`” which is the socket, “`filestream`” which is the text of the file to output, and “`contentType`” which is the HTML Content-Type. We construct the HTML header information according to the standard and prepend it to the file. The resulting string is output to the socket.

— package AXSERV AxiomServer —

```

outputToSocket(s:SExpression,filestream:String,contentType:String):Void ==
  filelength:String := string(#filestream)
  file:String := ""
  nl:String:=STRING(NewLine$Lisp)$Lisp
  file := concat ["Content-Length: ",filelength,nl,nl,file]
  file := concat ["Connection: close",nl,file]
  file := concat ["Content-Type: ",contentType,nl,file]
  file := concat ["HTTP/1.1 200 OK",nl,file]
  file := concat [file,filestream]
--   WriteLine(file)$Lisp

```

```
f:=MAKE_-STRING_-INPUT_-STREAM(file)$Lisp
SiCopyStream(f,s)$Lisp
CLOSE(f)$Lisp
CLOSE(s)$Lisp
```

---

### getCommand

The getCommand function is invoked when the HTTP request is a POST and contains the string "command". Essentially the game here is to rebind the various output streams used by Axiom so we can capture the normal output. This function returns a set of HTML 5 div blocks:

1. stepnum, the value of lastStep()
2. command, the value of the command variable
3. algebra, the value of the algebra variable
4. mathml, the value of the mathml variable
5. type, the value of lastType()

The HTML functions in the hyperdoc browser depend on the order of these variables so do not change this without changing the corresponding functions in the browser HTML.

— package AXSERV AxiomServer —

```
getCommand(s:SExpression,command:String):Void ==
  WriteLine$Lisp concat ["getCommand: ",command]
  SETQ(tmpmathml$Lisp, MAKE_-STRING_-OUTPUT_-STREAM())$Lisp$Lisp
  SETQ(tmpalgebra$Lisp, MAKE_-STRING_-OUTPUT_-STREAM())$Lisp$Lisp
  SETQ(savemathml$Lisp, _$texOutputStream$Lisp)$Lisp
  SETQ(savealgebra$Lisp, _$algebraOutputStream$Lisp)$Lisp
  SETQ(_$texOutputStream$Lisp,tmpmathml$Lisp)$Lisp
  SETQ(_$algebraOutputStream$Lisp,tmpalgebra$Lisp)$Lisp
  ans := string parseAndEvalToStringEqNum$Lisp command
  SETQ(resultmathml$Lisp,_
    GET_-OUTPUT_-STREAM_-STRING(_$texOutputStream$Lisp)$Lisp)$Lisp
  SETQ(resultalgebra$Lisp,_
    GET_-OUTPUT_-STREAM_-STRING(_$algebraOutputStream$Lisp)$Lisp)$Lisp
  SETQ(_$texOutputStream$Lisp,savemathml$Lisp)$Lisp
  SETQ(_$algebraOutputStream$Lisp,savealgebra$Lisp)$Lisp
  CLOSE(tmpmathml$Lisp)$Lisp
  CLOSE(tmpalgebra$Lisp)$Lisp
  -- Since strings returned from axiom are going to be displayed in html I
  -- should really check for the characters &,<,> and replace them with
  -- &amp;,&lt;,&gt;.
```

```

-- At present I only check for ampersands in formatMessages.
mathml:String := string(resultmathml$Lisp)
algebra:String := string(resultalgebra$Lisp)
algebra := formatMessages(algebra)
-- At this point mathml contains the mathml for the output but does not
-- include step number or type information.
-- We should also save the command.
-- I get the type and step number from the $internalHistoryTable
axans:String := _
  concat ["<div class=_\"stepnum_\">", lastStep(), "</div>_
    <div class=_\"command_\">", command, "</div>_
    <div class=_\"algebra_\">", algebra, "</div>_
    <div class=_\"mathml_\">", mathml, "</div>_
    <div class=_\"type_\">", lastType(), "</div>"]
--      WriteLine$Lisp concat ["mathml answer: ", mathml]
--      WriteLine$Lisp concat ["algebra answer: ", algebra]
q:=MAKE_-STRING_-INPUT_-STREAM(axans)$Lisp
SiCopyStream(q,s)$Lisp
CLOSE(q)$Lisp
CLOSE(s)$Lisp

```

---

### getInterp

The `getInterp` function is invoked when the HTTP request is a POST and contains the string "command". Essentially the game here is to rebind the various output streams used by Axiom so we can capture the normal output. This function returns a set of HTML 5 div blocks:

1. `stepnum`, the value of `lastStep()`
2. `command`, the value of the command variable
3. `algebra`, the value of the algebra variable
4. `mathml`, the value of the `mathml` variable
5. `type`, the value of `lastType()`

The HTML functions in the hyperdoc browser depend on the order of these variables so do not change this without changing the corresponding functions in the browser HTML.

— package **AXSERV** **AxiomServer** —

```

getInterp(s:SExpression,command:String):Void ==
  WriteLine$Lisp concat ["getInterp: ",command]
  SETQ(tmpmathml$Lisp, MAKE_-STRING_-OUTPUT_-STREAM()$Lisp)$Lisp
  SETQ(tmpalgebra$Lisp, MAKE_-STRING_-OUTPUT_-STREAM()$Lisp)$Lisp

```

```

SETQ(savemathml$Lisp, _$texOutputStream$Lisp)$Lisp
SETQ(savealgebra$Lisp, _$algebraOutputStream$Lisp)$Lisp
SETQ(_$texOutputStream$Lisp,tmpmathml$Lisp)$Lisp
SETQ(_$algebraOutputStream$Lisp,tmpalgebra$Lisp)$Lisp
ans := string parseAndEvalToStringEqNum$Lisp command
SETQ(resultmathml$Lisp,_
      GET_-OUTPUT_-STREAM_-STRING(_$texOutputStream$Lisp)$Lisp)$Lisp
SETQ(resultalgebra$Lisp,_
      GET_-OUTPUT_-STREAM_-STRING(_$algebraOutputStream$Lisp)$Lisp)$Lisp
SETQ(_$texOutputStream$Lisp,savemathml$Lisp)$Lisp
SETQ(_$algebraOutputStream$Lisp,savealgebra$Lisp)$Lisp
CLOSE(tmpmathml$Lisp)$Lisp
CLOSE(tmpalgebra$Lisp)$Lisp
-- Since strings returned from axiom are going to be displayed in html I
-- should really check for the characters &,<,> and replace them with
-- &amp;,&lt;,&gt;.
-- At present I only check for ampersands in formatMessages.
mathml:String := string(resultmathml$Lisp)
algebra:String := string(resultalgebra$Lisp)
algebra := formatMessages(algebra)
-- At this point mathml contains the mathml for the output but does not
-- include step number or type information.
-- We should also save the command.
-- I get the type and step number from the $internalHistoryTable
axans:String := _
  concat ["<div class=\"stepnum_>", lastStep(), "</div>_
        <div class=\"command_>", command, "</div>_
        <div class=\"algebra_>",algebra,"</div>_
        <div class=\"mathml_>",mathml,"</div>_
        <div class=\"type_>",lastType(),"</div>"]
-- WriteLine$Lisp concat ["mathml answer: ",mathml]
-- WriteLine$Lisp concat ["algebra answer: ",algebra]
q:=MAKE_-STRING_-INPUT_-STREAM(axans)$Lisp
SiCopyStream(q,s)$Lisp
CLOSE(q)$Lisp
CLOSE(s)$Lisp

```

### getLisp

The getLisp function is invoked when the HTTP request is a POST and contains the string "lispcall".

— package AXSERV AxiomServer —

```

getLisp(s:SExpression,command:String):Void ==
  WriteLine$Lisp concat ["getLisp: ",command]
  evalresult:=EVAL(READ_-FROM_-STRING(command)$Lisp)$Lisp

```

```

mathml:String:=string(evalresult)
--      WriteLine$Lisp concat ["getLisp: after ",mathml]
--      WriteLine$Lisp concat ["getLisp output: ",mathml]
SETQ(tmpalgebra$Lisp, MAKE_-STRING_-OUTPUT_-STREAM()$Lisp)$Lisp
SETQ(savemathml$Lisp, _$texOutputStream$Lisp)$Lisp
SETQ(savealgebra$Lisp, _$algebraOutputStream$Lisp)$Lisp
SETQ(_$texOutputStream$Lisp,tmpmathml$Lisp)$Lisp
SETQ(_$algebraOutputStream$Lisp,tmpalgebra$Lisp)$Lisp
SETQ(resultalgebra$Lisp,_
      GET_-OUTPUT_-STREAM_-STRING(_$algebraOutputStream$Lisp)$Lisp)$Lisp
SETQ(_$texOutputStream$Lisp,savemathml$Lisp)$Lisp
SETQ(_$algebraOutputStream$Lisp,savealgebra$Lisp)$Lisp
CLOSE(tmpalgebra$Lisp)$Lisp
-- Since strings returned from axiom are going to be displayed in html I
-- should really check for the characters &,<,> and replace them with
-- &amp;,&lt;,&gt;.
-- At present I only check for ampersands in formatMessages.
algebra:String := string(resultalgebra$Lisp)
algebra := formatMessages(algebra)
-- At this point mathml contains the mathml for the output but does not
-- include step number or type information.
-- We should also save the command.
-- I get the type and step number from the $internalHistoryTable
axans:String := _
  concat ["<div class=\"stepnum_>", lastStep(), "</div>_
    <div class=\"command_>", command, "</div>_
    <div class=\"algebra_>",algebra,"</div>_
    <div class=\"mathml_>",mathml,"</div>_
    <div class=\"type_>",lastType(),"</div>"]
--      WriteLine$Lisp concat ["mathml answer: ",mathml]
--      WriteLine$Lisp concat ["algebra answer: ",algebra]
q:=MAKE_-STRING_-INPUT_-STREAM(axans)$Lisp
SiCopyStream(q,s)$Lisp
CLOSE(q)$Lisp
CLOSE(s)$Lisp

```

### getShow

The getShow function is invoked when the HTTP request is a POST and contains the string "showcall". The )show command generates output to lisp's \*standard-output\* so we wrap that stream to capture it. The resulting string needs to be transformed into html-friendly form. This is done in the call to replace-entitites (see http.lisp)

— package AXSERV AxiomServer —

```

getShow(s:SExpression,showarg:String):Void ==
  WriteLine$Lisp concat ["getShow: ",showarg]

```

```

realarg:=SUBSEQ(showarg,6)$Lisp
show:=_
"(progn (setq |$options| '(|operations|))) (|show| '|" realarg "|))"

CLOSE(q)$Lisp
CLOSE(s)$Lisp

```

---

**lastType**

To examine the `$internalHistoryTable` use the following line

```
)lisp |$internalHistoryTable|
```

We need to pick out first member of `internalHistoryTable` and then pick out the element with `%` as first element. Here is an example showing just the first element of the list, which corresponds to the last command.

Note that the last command does not necessarily correspond to the last element of the first element of `$internalHistoryTable` as it is in this example.

```
(
  (4 NIL
   (x (value (BasicOperator) WRAPPED . #<vector 09a93bd0>))
   (y (value (BasicOperator) WRAPPED . #<vector 09a93bb4>))
   (% (value (Matrix (Polynomial (Integer))) WRAPPED . #<vector 0982e0e0>))
  )
  ...
)
```

We also need to check for input error in which case the `$internalHistoryTable` is not changed and the type retrieved would be that for the last correct input.

— package **AXSERV** **AxiomServer** —

### 3.1 package BALFACT BalancedFactorisation

#### 3.1.1 BalancedFactorisation (BALFACT)

#### Exports:

balancedFactorisation

— package BALFACT BalancedFactorisation —

```
)abbrev package BALFACT BalancedFactorisation
++ Author: Manuel Bronstein
++ Date Created: 1 March 1991
++ Date Last Updated: 11 October 1991
++ Description:
++ This package provides balanced factorisations of polynomials.
```

```
BalancedFactorisation(R, UP): Exports == Implementation where
  R : Join(GcdDomain, CharacteristicZero)
```

```

UP : UnivariatePolynomialCategory R

Exports ==> with
  balancedFactorisation: (UP, UP) -> Factored UP
  ++ balancedFactorisation(a, b) returns
  ++ a factorisation \spad{a = p1^e1 ... pm^em} such that each
  ++ \spad{pi} is balanced with respect to b.
  balancedFactorisation: (UP, List UP) -> Factored UP
  ++ balancedFactorisation(a, [b1,...,bn]) returns
  ++ a factorisation \spad{a = p1^e1 ... pm^em} such that each
  ++ pi is balanced with respect to \spad{[b1,...,bm]}.

Implementation ==> add
  balSqfr : (UP, Integer, List UP) -> Factored UP
  balSqfr1: (UP, Integer,      UP) -> Factored UP

  balancedFactorisation(a:UP, b:UP) == balancedFactorisation(a, [b])

  balSqfr1(a, n, b) ==
    g := gcd(a, b)
    fa := sqfrFactor((a exquo g)::UP, n)
    ground? g => fa

## 3.2 package BOP1 BasicOperatorFunctions1

### 3.2.1 BasicOperatorFunctions1 (BOP1)

#### Exports:

constantOpIfCan constantOperator derivative evaluate

— package BOP1 BasicOperatorFunctions1 —

```

)abbrev package BOP1 BasicOperatorFunctions1
++ Author: Manuel Bronstein
++ Date Created: 28 Mar 1988
++ Date Last Updated: 15 May 1990
++ Keywords: operator.
++ Description:
++ This package exports functions to set some commonly used properties
++ of operators, including properties which contain functions.

BasicOperatorFunctions1(A:SetCategory): Exports == Implementation where
  OP ==> BasicOperator
  EVAL ==> "%eval"
  CONST ==> "%constant"
  DIFF ==> "%diff"
  OUT ==> OutputForm
  IN ==> InputForm

Exports ==> with
  evaluate : (OP, List A) -> Union(A, "failed")
  ++ evaluate(op, [a1,...,an]) checks if op has an "%eval"
  ++ property f. If it has, then \spad{f(a1,...,an)} is returned, and
  ++ "failed" otherwise.
  evaluate : (OP, List A -> A) -> OP
  ++ evaluate(op, foo) attaches foo as the "%eval" property
  ++ of op. If op has an "%eval" property f, then applying op
  ++ to \spad{(a1,...,an)} returns the result of \spad{f(a1,...,an)}.
  evaluate : (OP, A -> A) -> OP

```

```

++ evaluate(op, foo) attaches foo as the "%eval" property
++ of op. If op has an "%eval" property f, then applying op
++ to a returns the result of \spad{f(a)}. Argument op must be unary.
evaluate      : OP                      -> Union(List A -> A, "failed")
++ evaluate(op) returns the value of the "%eval" property of
++ op if it has one, and "failed" otherwise.
derivative    : (OP, List (List A -> A)) -> OP
++ derivative(op, [foo1,...,foon]) attaches [foo1,...,foon] as
++ the "%diff" property of op. If op has an "%diff" property
++ \spad{f1,...,fn} then applying a derivation D
++ to \spad{op(a1,...,an)}
++ returns \spad{f1(a1,...,an) * D(a1) + ... + fn(a1,...,an) * D(an)}.
derivative    : (OP, A -> A) -> OP
++ derivative(op, foo) attaches foo as the "%diff" property
++ of op. If op has an "%diff" property f, then applying a
++ derivation D to op(a) returns \spad{f(a) * D(a)}.
++ Argument op must be unary.
derivative    : OP -> Union(List(List A -> A), "failed")
++ derivative(op) returns the value of the "%diff" property of
++ op if it has one, and "failed" otherwise.
if A has OrderedSet then
  constantOperator: A -> OP
  ++ constantOperator(a) returns a nullary operator op
  ++ such that \spad{op()} always evaluate to \spad{a}.
  constantOpIfCan : OP -> Union(A, "failed")
  ++ constantOpIfCan(op) returns \spad{a} if op is the constant
  ++ nullary operator always returning \spad{a}, "failed" otherwise.

Implementation ==> add

=====
Bezier Curve examples
=====
```

A linear Bezier curve is a simple interpolation between the starting point and the ending point based on a parameter  $t$ .

Given a start point  $a=[x_1,y_1]$  and an endpoint  $b=[x_2,y_2]$   
 $f(t) == [(1-t)*x_1 + t*x_2, (1-t)*y_1 + t*y_2]$

```
n:=linearBezier([2.0,2.0],[4.0,4.0])
  theMap(BEZIER;linearBezier;2LM;1!0,707)
```

```
[n(t/10.0) for t in 0..10 by 1]
[[2.0,2.0], [2.2,2.2], [2.4,2.4], [2.6,2.6], [2.8,2.8], [3.0,3.0],
 [3.2,3.2], [3.4,3.4], [3.6,3.6], [3.8,3.8], [4.0,4.0]]
```

A quadratic Bezier curve is a simple interpolation between the starting point, a middle point, and the ending point based on a parameter  $t$ .

Given a start point  $a=[x_1,y_1]$ , a middle point  $b=[x_2,y_2]$ ,  
 and an endpoint  $c=[x_3,y_3]$

$$f(t) == [(1-t)^2 x_1 + 2t(1-t) x_2 + t^2 x_3, \\ (1-t)^2 y_1 + 2t(1-t) y_2 + t^2 y_3]$$

```
n:=quadraticBezier([2.0,2.0],[4.0,4.0],[6.0,2.0])
  theMap(BEZIER;quadraticBezier;3LM;2!0,291)
```

```
[n(t/10.0) for t in 0..10 by 1]
[[2.0,2.0], [2.4,2.36], [2.8,2.64], [3.2,2.84], [3.6,2.96], [4.0,3.0],
 [4.4,2.96], [4.8,2.84], [5.2,2.64], [5.6,2.36], [6.0,2.0]]
```

A cubic Bezier curve is a simple interpolation between the starting point, a left-middle point,, a right-middle point, and the ending point based on a parameter  $t$ .

Given a start point  $a=[x1,y1]$ , the left-middle point  $b=[x2,y2]$ , the right-middle point  $c=[x3,y3]$  and an endpoint  $d=[x4,y4]$

```
f(t) == [(1-t)^3 x1 + 3t(1-t)^2 x2 + 3t^2 (1-t) x3 + t^3 x4,
          (1-t)^3 y1 + 3t(1-t)^2 y2 + 3t^2 (1-t) y3 + t^3 y4]
```

```
n:=cubicBezier([2.0,2.0],[2.0,4.0],[6.0,4.0],[6.0,2.0])
theMap(BEZIER;cubicBezier;4LM;3!0,915)
```

```
[n(t/10.0) for t in 0..10 by 1]
[[2.0,2.0], [2.112,2.54], [2.416,2.96], [2.864,3.26], [3.408,3.44],
 [4.0,3.5], [4.592,3.44], [5.136,3.26], [5.584,2.96], [5.888,2.54],
 [6.0,2.0]]
```

Bezier curves "move" based on moving their control points, which in the case of the three components of a quadratic Bezier curve are the three points given. To see this motion we can show what happens when you "drag" the middle control point along the line from  $[-4,4]$  to  $[4,4]$  by increments of 1.

First, we form the line as a list of Floats, 9 in all.

```
line:=[[i::Float,4.0] for i in -4..4 by 1]
```

Next, we form a list of functions, each with a different center control point. Notice that the endpoints remain fixed so we expect that the curve will begin and end at the same point but that the midpoint is pulled around.

```
functions:=[quadraticBezier([2.0,2.0],m,[6.0,2.0]) for m in line]
```

Then we form a list of the graphs by calling each function in the above list. Each function call happens 101 times (to include both endpoints). Thus we get a List of Lists of Points of DoubleFloats

```
graphs:= [ [ point( ( functions.i)(j/100.0) )::LIST(DFLOAT) ) _
            for j in 0..100] for i in 1..9]
```

We draw the first graph to see if it looks reasonable:

```
d1:=draw(graphs.1)
```

Since it does we add the other 8 graphs. The 2D graphs can hold up to 9 simultaneous graphs.

```
others:=[graphs.i for i in 2..9]
for i in 2..9 for graph in others repeat putGraph(d1,[graph],i)
```

and now we display them all on one graph.

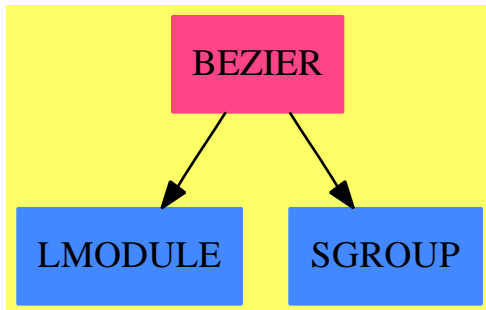

```
vp:=makeViewport2D(d1)
```

## 3.6 package BOUNDZRO BoundIntegerRoots

### 3.6.1 BoundIntegerRoots (BOUNDZRO)

**Exports:**

integerBound

— package BOUNDZRO BoundIntegerRoots —

```

)abbrev package BOUNDZRO BoundIntegerRoots
++ Author: Manuel Bronstein
++ Date Created: 11 March 1991
++ Date Last Updated: 18 November 1991
++ Description:
++ \spadtype{BoundIntegerRoots} provides functions to
++ find lower bounds on the integer roots of a polynomial.

BoundIntegerRoots(F, UP): Exports == Implementation where
  F : Join(Field, RetractableTo Fraction Integer)
  UP : UnivariatePolynomialCategory F

Z ==> Integer
Q ==> Fraction Z
K ==> Kernel F
UPQ ==> SparseUnivariatePolynomial Q
ALGOP ==> "%alg"

Exports ==> with
  integerBound: UP -> Z
    ++ integerBound(p) returns a lower bound on the negative integer
    ++ roots of p, and 0 if p has no negative integer roots.

Implementation ==> add
  import RationalFactorize(UPQ)
  import UnivariatePolynomialCategoryFunctions2(F, UP, Q, UPQ)

  qbound : (UP, UPQ) -> Z
  zroot1 : UP -> Z
  qzroot1: UPQ -> Z
  negint : Q -> Z

-- returns 0 if p has no integer root < 0, its negative integer root otherwise
  qzroot1 p == negint(- leadingCoefficient(reductum p) / leadingCoefficient p)

-- returns 0 if p has no integer root < 0, its negative integer root otherwise
  zroot1 p ==
    z := - leadingCoefficient(reductum p) / leadingCoefficient p
    (r := retractIfCan(z)@Union(Q, "failed")) case Q => negint(r::Q)
    0

-- returns 0 if r is not a negative integer, r otherwise
  negint r ==
    ((u := retractIfCan(r)@Union(Z, "failed")) case Z) and (u::Z < 0) => u::Z

```

```

0

if F has ExpressionSpace then
  bringDown: F -> Q

-- the random substitution used by bringDown is NOT always a ring-homomorphism
-- (because of potential algebraic kernels), but is ALWAYS a Z-linear map.
-- this guarantees that bringing down the coefficients of (x + n) q(x) for an
-- integer n yields a polynomial h(x) which is divisible by x + n
-- the only problem is that evaluating with random numbers can cause a
-- division by 0. We should really be able to trap this error later and
-- reevaluate with a new set of random numbers    MB 11/91
bringDown f ==
  t := tower f

      | |          --+  f(i,x)
      i= 1          i= 1
```

Type: Expression Integer

The binomial(n, r) returns the number of subsets of r objects  
taken among n objects, i.e.  $n!/(r! * (n-r)!)$

The binomial coefficients are the coefficients of the series expansion  
of a power of a binomial, that is

```

      n
  ---+ / n \  k          n
>    |    | x  = (1 + x)
  ---+ \ k /
      k= 0
```

This leads to the famous pascal triangle. First we expose the OutputForm  
domain, which is normally hidden, so we can use it to format the lines.

```
)set expose add constructor OutputForm
```

Next we define a function that will output the list of binomial coefficients right justified with proper spacing:

```
pascalRow(n) == [right(binomial(n,i),4) for i in 0..n]
```

and now we format the whole line so that it looks centered:

```
displayRow(n)==output center blankSeparate pascalRow(n)
```

and we compute the triangle

```
for i in 0..7 repeat displayRow i
```

giving the pretty result:

```
Compiling function pascalRow with type NonNegativeInteger -> List
  OutputForm
Compiling function displayRow with type NonNegativeInteger -> Void
```

```

      1
     1 1
    1 2 1
   1 3 3 1
  1 4 6 4 1
 1 5 10 10 5 1
1 6 15 20 15 6 1
1 7 21 35 35 21 7 1
```

product	summation	***?		

#### binomial

We currently simplify binomial coefficients only for non-negative integral second argument, using the formula

$$\binom{n}{k} = \frac{1}{k!} \prod_{i=0..k-1} (n-i),$$

except if the second argument is symbolic: in this case  $\text{binomial}(n,n)$  is simplified to one.

Note that there are at least two different ways to define binomial coefficients for negative integral second argument. One way, particular suitable for combinatorics, is to set the binomial coefficient equal to zero for negative second argument. This is, partially, also the approach taken in `combinat.spad`, where we find

```
binomial(n, m) ==
  n < 0 or m < 0 or m > n => 0
  m = 0 => 1
```

Of course, here  $n$  and  $m$  are integers. This definition agrees with the recurrence

$$\binom{n}{k} + \binom{n}{k+1} = \binom{n+1}{k+1}.$$

Alternatively, one can use the formula

$$\binom{n}{k} = \frac{\Gamma(n+1)}{\Gamma(k+1)\Gamma(n-k+1)},$$

and leave the case where  $k \in \mathbf{Z}$ ,  $n \in \mathbf{Z}$  and  $k \leq n < 0$  undefined, since the limit does not exist in this case:

Since we then have that  $n - k + 1 \geq 1$ ,  $\Gamma(n - k + 1)$  is finite. So it is sufficient to consider  $\frac{\Gamma(n+1)}{\Gamma(k+1)}$ . On the one hand, we have

$$\lim_{n_0 \rightarrow n} \lim_{k_0 \rightarrow k} \frac{\Gamma(n_0 + 1)}{\Gamma(k_0 + 1)} = 0,$$

since for any non-integral  $n_0$ ,  $\Gamma(n_0 + 1)$  is finite. On the other hand,

$$\lim_{k_0 \rightarrow k} \lim_{n_0 \rightarrow n} \frac{\Gamma(n_0 + 1)}{\Gamma(k_0 + 1)}$$

does not exist, since for non-integral  $k_0$ ,  $\Gamma(k_0 + 1)$  is finite while  $\Gamma(n_0 + 1)$  is unbounded.

However, since for  $k \in \mathbf{Z}$ ,  $n \in \mathbf{Z}$  and  $0 < k < n$  both definitions agree, one could also combine them. This is what, for example, Mathematica does. It seems that MuPAD sets  $\text{binomial}(n, n) = 1$  for all arguments  $n$ , and returns  $\text{binomial}(-2, n)$  unevaluated. Provisos may help here.

#### **dvsum and dvdsum**

The `dvsum` and `dvdsum` operations implement differentiation of sums with and without bounds. Note that the function

$$n \mapsto \sum_{k=1}^n f(k, n)$$

is well defined only for integral values of  $n$  greater than or equal to zero. There is not even consensus how to define this function for  $n < 0$ . Thus, it is not differentiable. Therefore, we need to check whether we erroneously are differentiating with respect to the upper bound or the lower bound, where the same reasoning holds.

Differentiating a sum with respect to its indexing variable correctly gives zero. This is due to the introduction of dummy variables in the internal representation of a sum: the operator `%defsum` takes 5 arguments, namely

1. the summands, where each occurrence of the indexing variable is replaced by
2. the dummy variable,
3. the indexing variable,
4. the lower bound, and
5. the upper bound.

**dvprod and dvdprod**

The dvprod and dvdprod operations implement differentiation of products with and without bounds. Note again, that we cannot even properly define products with bounds that are not integral.

To differentiate the product, we use Leibniz rule:

$$\frac{d}{dx} \prod_{i=a}^b f(i, x) = \sum_{i=a}^b \frac{\frac{d}{dx} f(i, x)}{f(i, x)} \prod_{i=a}^b f(i, x)$$

There is one situation where this definition might produce wrong results, namely when the product is zero, but axiom failed to recognize it: in this case,

$$\frac{d}{dx} f(i, x) / f(i, x)$$

is undefined for some  $i$ . However, I was not able to come up with an example. The alternative definition

$$\frac{d}{dx} \prod_{i=a}^b f(i, x) = \sum_{i=a}^b \left( \frac{d}{dx} f(i, x) \right) \prod_{j=a, j \neq i}^b f(j, x)$$

has the slight (display) problem that we would have to come up with a new index variable, which looks very ugly. Furthermore, it seems to me that more simplifications will occur with the first definition.

```
f := operator 'f
D(product(f(i,x),i=1..m),x)
```

**dvpow2**

The dvpow2 operation implements the differentiation of the power operator %power with respect to its second argument, i.e., the exponent. It uses the formula

$$\frac{d}{dx} g(y)^x = \frac{d}{dx} e^{x \log g(y)} = \log g(y) g(y)^x.$$

If  $g(y)$  equals zero, this formula is not valid, since the logarithm is not defined there. Although strictly speaking  $0^x$  is not differentiable at zero, we return zero for convenience.

## 4.16 package CRFP ComplexRootFindingPackage

### 4.16.1 ComplexRootFindingPackage (CRFP)

#### Exports:

complexZeros	divisorCascade	factor	graeffe	norm
pleskenSplit	reciprocalPolynomial	rootRadius	schwerpunkt	setErrorBound
startPolynomial				

— package CRFP ComplexRootFindingPackage —

```
)abbrev package CRFP ComplexRootFindingPackage
++ Author: J. Grabmeier
++ Date Created: 31 January 1991
++ Date Last Updated: 12 April 1991
++ Basic Operations: factor, pleskenSplit
++ Related Constructors:
++ Also See:
++ AMS Classifications:
++ Keywords: complex zeros, roots
++ References: J. Grabmeier: On Plesken's root finding algorithm,
++ in preparation
++ A. Schoenhage: The fundamental theorem of algebra in terms of computational
++ complexity, preliminary report, Univ. Tuebingen, 1982
++ Description:
++ \spadtype{ComplexRootFindingPackage} provides functions to
++ find all roots of a polynomial p over the complex number by
++ using Plesken's idea to calculate in the polynomial ring
++ modulo f and employing the Chinese Remainder Theorem.
++ In this first version, the precision (see digits)
```

```

++ is not increased when this is necessary to
++ avoid rounding errors. Hence it is the user's responsibility to
++ increase the precision if necessary.
++ Note also, if this package is called with e.g. \spadtype{Fraction Integer},
++ the precise calculations could require a lot of time.
++ Also note that evaluating the zeros is not necessarily a good check
++ whether the result is correct: already evaluation can cause
++ rounding errors.

ComplexRootFindingPackage(R, UP): public == private where
  -- R : Join(Field, OrderedRing, CharacteristicZero)
  -- Float not in CharacteristicZero !!
  R : Join(Field, OrderedRing)
  UP : UnivariatePolynomialCategory Complex R

public ==> with
  complexZeros : UP -> L C
    ++ complexZeros(p) tries to determine all complex zeros
    ++ of the polynomial p with accuracy given by the package
    ++ constant globalEps which you may change by setErrorBound.
  complexZeros : (UP, R) -> L C
    ++ complexZeros(p, eps) tries to determine all complex zeros
    ++ of the polynomial p with accuracy given by eps.
  divisorCascade : (UP,UP, Boolean) -> L FAE
    ++ divisorCascade(p,tp) assumes that degree of polynomial tp
    ++ is smaller than degree of polynomial p, both monic.
    ++ A sequence of divisions are calculated
    ++ using the remainder, made monic, as divisor
    ++ for the the next division. The result contains also the error of the
    ++ factorizations, i.e. the norm of the remainder polynomial.
    ++ If info is true, then information messages are issued.
  divisorCascade : (UP,UP) -> L FAE
    ++ divisorCascade(p,tp) assumes that degree of polynomial tp
    ++ is smaller than degree of polynomial p, both monic.
    ++ A sequence of divisions is calculated
    ++ using the remainder, made monic, as divisor
    ++ for the the next division. The result contains also the error of the
    ++ factorizations, i.e. the norm of the remainder polynomial.
  factor: (UP,R,Boolean) -> FR UP
    ++ factor(p, eps, info) tries to factor p into linear factors
    ++ with error atmost eps. An overall error bound

```

```

++ eps0 is determined and iterated tree-like calls
++ to pleskenSplit are used to get the factorization.
++ If info is true, then information messages are given.
factor: (UP,R) -> FR UP
++ factor(p, eps) tries to factor p into linear factors
++ with error atmost eps. An overall error bound
++ eps0 is determined and iterated tree-like calls
++ to pleskenSplit are used to get the factorization.
factor: UP -> FR UP
++ factor(p) tries to factor p into linear factors
++ with error atmost globalEps, the internal error bound,
++ which can be set by setErrorBound. An overall error bound
++ eps0 is determined and iterated tree-like calls
++ to pleskenSplit are used to get the factorization.
graeffe : UP -> UP
++ graeffe p determines q such that \spad{q(-z**2) = p(z)*p(-z)}.
++ Note that the roots of q are the squares of the roots of p.
norm : UP -> R
++ norm(p) determines sum of absolute values of coefficients
++ Note that this function depends on abs.
pleskenSplit: (UP, R, Boolean) -> FR UP
++ pleskenSplit(poly,eps,info) determines a start polynomial start
++ by using "startPolynomial then it increases the exponent
++ n of start ** n mod poly to get an approximate factor of
++ poly, in general of degree "degree poly -1". Then a divisor
++ cascade is calculated and the best splitting is chosen, as soon
++ as the error is small enough.
--++ In a later version we plan
--++ to use the whole information to get a split into more than 2
--++ factors.
++ If info is true, then information messages are issued.
pleskenSplit: (UP, R) -> FR UP
++ pleskenSplit(poly, eps) determines a start polynomial start
++ by using "startPolynomial then it increases the exponent
++ n of start ** n mod poly to get an approximate factor of
++ poly, in general of degree "degree poly -1". Then a divisor
++ cascade is calculated and the best splitting is chosen, as soon
++ as the error is small enough.
--++ In a later version we plan
--++ to use the whole information to get a split into more than 2
--++ factors.
reciprocalPolynomial: UP -> UP
++ reciprocalPolynomial(p) calculates a polynomial which has exactly
++ the inverses of the non-zero roots of p as roots, and the same
++ number of 0-roots.
rootRadius: (UP,R) -> R
++ rootRadius(p,errQuot) calculates the root radius of p with a
++ maximal error quotient of errQuot.
rootRadius: UP -> R
++ rootRadius(p) calculates the root radius of p with a

```

```

++ maximal error quotient of  $1 + \text{globalEps}$ , where
++ globalEps is the internal error bound, which can be
++ set by setErrorBound.
schwerpunkt: UP -> C
++ schwerpunkt(p) determines the 'Schwerpunkt' of the roots of the
++ polynomial p of degree n, i.e. the center of gravity, which is
++ coefficient of  $\text{spad}\{x^{n-1}\}$  divided by
++ n times coefficient of  $\text{spad}\{x^n\}$ .
setErrorBound : R -> R
++ setErrorBound(eps) changes the internal error bound,
-- by default being  $10 ** (-20)$  to eps, if R is
++ by default being  $10 ** (-3)$  to eps, if R is
++ a member in the category  $\text{spadtype}\{\text{QuotientFieldCategory Integer}\}$ .
++ The internal globalDigits is set to
++  $\lceil 1/r \rceil * 10$  being  $10**7$  by default.
startPolynomial: UP -> Record(start: UP, factors: FR UP)
++ startPolynomial(p) uses the ideas of Schoenhage's
++ variant of Graeffe's method to construct circles which separate
++ roots to get a good start polynomial, i.e. one whose
++ image under the Chinese Remainder Isomorphism has both entries
++ of norm smaller and greater or equal to 1. In case the
++ roots are found during internal calculations.
++ The corresponding factors
++ are in factors which are otherwise 1.

& + \frac{1}{240} (2 \ 1) + \frac{5}{5040} (1)
\end{aligned}$$

Type: SymmetricPolynomial Fraction Integer

The operation `elementary` computes the  $n$ -th elementary symmetric function for argument  $n$ .

$$\begin{aligned}
& \text{elementary } 7 \\
& \frac{1}{7} (7) - \frac{1}{6} (6 \ 1) - \frac{1}{10} (5 \ 2) + \frac{1}{10} (5 \ 1 \ 1) - \frac{2}{12} (4 \ 3) + \frac{1}{8} (4 \ 2 \ 1) - \frac{1}{24} (4 \ 1 \ 1) \\
& + \frac{1}{18} (3 \ 1) + \frac{2}{24} (3 \ 2) - \frac{1}{12} (3 \ 2 \ 1) + \frac{2}{72} (3 \ 1 \ 1) - \frac{1}{48} (2 \ 1) + \frac{3}{48} (2 \ 1 \ 1) \\
& + \frac{1}{240} (2 \ 1) + \frac{5}{5040} (1)
\end{aligned}$$

Type: SymmetricPolynomial Fraction Integer

The operation `alternating` returns the cycle index of the alternating group having an even number of even parts in each cycle partition.

$$\begin{aligned}
& \text{alternating } 7 \\
& \frac{2}{7} (7) + \frac{1}{5} (5 \ 1) + \frac{2}{4} (4 \ 2 \ 1) + \frac{1}{9} (3 \ 1) + \frac{2}{12} (3 \ 2) + \frac{1}{36} (3 \ 1 \ 1) + \frac{4}{24} (2 \ 1) \\
& + \frac{1}{2520} (1)
\end{aligned}$$

Type: SymmetricPolynomial Fraction Integer

The operation `cyclic` returns the cycle index of the cyclic group.

$$\begin{aligned}
& \text{cyclic } 7 \\
& \frac{6}{7} (7) + \frac{1}{7} (1)
\end{aligned}$$

Type: SymmetricPolynomial Fraction Integer

The operation `dihedral` is the cycle index of the dihedral group.

$$\text{dihedral } 7$$

$$\frac{3}{7} - \frac{1}{2} (7) + \frac{3}{2} - \frac{1}{14} (2 \ 1) + \frac{1}{14} - \frac{7}{14} (1)$$

Type: SymmetricPolynomial Fraction Integer

The operation graphs for argument n returns the cycle index of the group of permutations on the edges of the complete graph with n nodes induced by applying the symmetric group to the nodes.

$$\text{graphs } 5$$

$$\frac{1}{6} - \frac{1}{5} (6 \ 3 \ 1) + \frac{2}{5} - \frac{1}{4} (5) + \frac{2}{4} - \frac{1}{6} (4 \ 2) + \frac{3}{6} - \frac{1}{8} (3 \ 1) + \frac{4}{8} - \frac{2}{12} (2 \ 1) + \frac{4}{12} - \frac{3}{120} (2 \ 1 \ 3) + \frac{1}{120} - \frac{10}{120} (1)$$

Type: SymmetricPolynomial Fraction Integer

The cycle index of a direct product of two groups is the product of the cycle indices of the groups. Redfield provided two operations on two cycle indices which will be called "cup" and "cap" here. The cup of two cycle indices is a kind of scalar product that combines monomials for permutations with the same cycles. The cap operation provides the sum of the coefficients of the result of the cup operation which will be an integer that enumerates what Redfield called group-reduced distributions.

We can, for example, represent complete 2 \* complete 2 as the set of objects a a b b and complete 2 \* complete 1 \* complete 1 as c c d e.

This integer is the number of different sets of four pairs.

$$\frac{\text{cap}(\text{complete } 2^{**}2, \text{complete } 2 * \text{complete } 1^{**}2)}{4}$$

Type: Fraction Integer

For example,

$$\begin{array}{cccc} a & a & b & b \\ c & c & d & e \end{array} \quad \begin{array}{cccc} a & a & b & b \\ c & d & c & e \end{array} \quad \begin{array}{cccc} a & a & b & b \\ c & e & c & d \end{array} \quad \begin{array}{cccc} a & a & b & b \\ d & e & c & c \end{array}$$

This integer is the number of different sets of four pairs no two pairs being equal.

$$\frac{\text{cap}(\text{elementary } 2^{**}2, \text{complete } 2 * \text{complete } 1^{**}2)}{2}$$

Type: Fraction Integer

For example,

$$\begin{array}{cccc} a & a & b & b \\ c & d & c & e \end{array} \quad \begin{array}{cccc} a & a & b & b \\ c & e & c & d \end{array}$$

In this case the configurations enumerated are easily constructed,

however the theory merely enumerates them providing little help in actually constructing them.

Here are the number of 6-pairs, first from a a a b b c, second from d d e e f g.

```
cap(complete 3*complete 2*complete 1,complete 2**2*complete 1**2)
24
Type: Fraction Integer
```

Here it is again, but with no equal pairs.

```
cap(elementary 3*elementary 2*elementary 1,complete 2**2*complete 1**2)
8
Type: Fraction Integer
```

```
cap(complete 3*complete 2*complete 1,elementary 2**2*elementary 1**2)
8
Type: Fraction Integer
```

The number of 6-triples, first from a a a b b c, second from d d e e f g, third from h h i i j j.

```
eval(cup(complete 3*complete 2*complete 1, cup(complete 2**2*complete 1**2,complete 2**3)))
1500
Type: Fraction Integer
```

The cycle index of vertices of a square is dihedral 4.

```
square:=dihedral 4
1      3  2  1      2  1  4
- (4) + - (2 ) + - (2 1 ) + - (1 )
4      8      4      8
Type: SymmetricPolynomial Fraction Integer
```

The number of different squares with 2 red vertices and 2 blue vertices.

```
cap(complete 2**2,square)
2
Type: Fraction Integer
```

The number of necklaces with 3 red beads, 2 blue beads and 2 green beads.

```
cap(complete 3*complete 2**2,dihedral 7)
18
Type: Fraction Integer
```

The number of graphs with 5 nodes and 7 edges.

```
cap(graphs 5,complete 7*complete 3)
```

4

Type: Fraction Integer

The cycle index of rotations of vertices of a cube.

```
s(x) == powerSum(x)
```

Type: Void

```
cube:=(1/24)*(s 1**8+9*s 2**4 + 8*s 3**2*s 1**2+6*s 4**2)
```

$$- \frac{1}{4} \binom{2}{4} + - \frac{1}{3} \binom{2}{3} \binom{2}{1} + - \frac{1}{8} \binom{2}{2} \binom{4}{2} + -- \frac{1}{24} \binom{8}{1}$$

Type: SymmetricPolynomial Fraction Integer

The number of cubes with 4 red vertices and 4 blue vertices.

```
cap(complete 4**2,cube)
```

7

Type: Fraction Integer

The number of labeled graphs with degree sequence 2 2 2 1 1 with no loops or multiple edges.

```
cap(complete 2**3*complete 1**2,wreath(elementary 4,elementary 2))
```

7

Type: Fraction Integer

Again, but with loops allowed but not multiple edges.

```
cap(complete 2**3*complete 1**2,wreath(elementary 4,complete 2))
```

17

Type: Fraction Integer

Again, but with multiple edges allowed, but not loops

```
cap(complete 2**3*complete 1**2,wreath(complete 4,elementary 2))
```

10

Type: Fraction Integer

Again, but with both multiple edges and loops allowed

```
cap(complete 2**3*complete 1**2,wreath(complete 4,complete 2))
```

23

Type: Fraction Integer

Having constructed a cycle index for a configuration we are at liberty to evaluate the `s_i` components any way we please. For example we can produce enumerating generating functions. This is done by providing a function `f` on an integer `i` to the value required of `s_i`, and then evaluating `eval(f, cycleindex)`.

```
x: ULS(FRAC INT, 'x, 0) := 'x
x
Type: UnivariateLaurentSeries(Fraction Integer, x, 0)
```

```
ZeroOrOne: INT -> ULS(FRAC INT, 'x, 0)
Type: Void
```

```
Integers: INT -> ULS(FRAC INT, 'x, 0)
Type: Void
```

For the integers 0 and 1, or two colors.

```
ZeroOrOne n == 1+x**n
Type: Void
```

```
ZeroOrOne 5
5
1 + x
Type: UnivariateLaurentSeries(Fraction Integer, x, 0)
```

For the integers 0, 1, 2, ... we have this.

```
Integers n == 1/(1-x**n)
Type: Void
```

```
Integers 5
5 10 11
1 + x + x + 0(x )
Type: UnivariateLaurentSeries(Fraction Integer, x, 0)
```

The coefficient of  $x^n$  is the number of graphs with 5 nodes and  $n$  edges.

Note that there is an eval function that takes two arguments. It has the signature:

```
((Integer -> D1), SymmetricPolynomial Fraction Integer) -> D1
from EvaluateCycleIndicators D1 if D1 has ALGEBRA FRAC INT
```

This function is not normally exposed (it will not normally be considered in the list of eval functions) as it is only useful for this particular domain. To use it we ask that it be considered thus:

```
)expose EVALCYC
```

and now we can use it:

```
eval(ZeroOrOne, graphs 5)
2 3 4 5 6 7 8 9 10 11
1 + x + 2x + 4x + 6x + 6x + 4x + 2x + x + x + 0(x )
```

Type: UnivariateLaurentSeries(Fraction Integer,x,0)

The coefficient of  $x^n$  is the number of necklaces with  $n$  red beads and  $n-8$  green beads.

```
eval(ZeroOrOne,dihedral 8)
      2      3      4      5      6      7      8
1 + x + 4x + 5x + 8x + 5x + 4x + x + x
Type: UnivariateLaurentSeries(Fraction Integer,x,0)
```

The coefficient of  $x^n$  is the number of partitions of  $n$  into 4 or fewer parts.

```
eval(Integers,complete 4)
      2      3      4      5      6      7      8      9      10      11
1 + x + 2x + 3x + 5x + 6x + 9x + 11x + 15x + 18x + 23x + 0(x )
Type: UnivariateLaurentSeries(Fraction Integer,x,0)
```

The coefficient of  $x^n$  is the number of partitions of  $n$  into 4 boxes containing ordered distinct parts.

```
eval(Integers,elementary 4)
      6      7      8      9      10      11      12      13      14      15      16
x + x + 2x + 3x + 5x + 6x + 9x + 11x + 15x + 18x + 23x
+
      17
0(x )
Type: UnivariateLaurentSeries(Fraction Integer,x,0)
```

The coefficient of  $x^n$  is the number of different cubes with  $n$  red vertices and  $8-n$  green ones.

```
eval(ZeroOrOne,cube)
      2      3      4      5      6      7      8
1 + x + 3x + 3x + 7x + 3x + 3x + x + x
Type: UnivariateLaurentSeries(Fraction Integer,x,0)
```

The coefficient of  $x^n$  is the number of different cubes with integers on the vertices whose sum is  $n$ .

```
eval(Integers,cube)
      2      3      4      5      6      7      8      9      10
1 + x + 4x + 7x + 21x + 37x + 85x + 151x + 292x + 490x + 848x
+
      11
0(x )
Type: UnivariateLaurentSeries(Fraction Integer,x,0)
```

The coefficient of  $x^n$  is the number of graphs with 5 nodes and with integers on the edges whose sum is  $n$ . In other words, the enumeration is of multigraphs with 5 nodes and  $n$  edges.

```
eval(Integers,graphs 5)
      2      3      4      5      6      7      8      9      10
      1 + x + 3x + 7x + 17x + 35x + 76x + 149x + 291x + 539x + 974x
+
      11
      0(x )
Type: UnivariateLaurentSeries(Fraction Integer,x,0)
```

Graphs with 15 nodes enumerated with respect to number of edges.

```
eval(ZeroOrOne ,graphs 15)
      2      3      4      5      6      7      8      9      10
      1 + x + 2x + 5x + 11x + 26x + 68x + 177x + 496x + 1471x + 4583x
+
      11
      0(x )
Type: UnivariateLaurentSeries(Fraction Integer,x,0)
```

Necklaces with 7 green beads, 8 white beads, 5 yellow beads and 10 red beads.

```
cap(dihedral 30,complete 7*complete 8*complete 5*complete 10)
49958972383320
Type: Fraction Integer
```

The operation SFunction is the S-function or Schur function of a partition written as a descending list of integers expressed in terms of power sum symmetric functions.

In this case the argument partition represents a tableau shape. For example 3,2,2,1 represents a tableau with three boxes in the first row, two boxes in the second and third rows, and one box in the fourth row. SFunction [3,2,2,1] counts the number of different tableaux of shape 3, 2, 2, 1 filled with objects with an ascending order in the columns and a non-descending order in the rows.

```
sf3221:= SFunction [3,2,2,1]
      1      1      2      1      2      1      1      4      1      2
      -- (6 2) - -- (6 1 ) - -- (4 ) + -- (4 3 1) + -- (4 1 ) - -- (3 2)
      12      12      16      12      24      36
+
      1      2 2      1      2      1      3      1      5      1      4      1      3 2
      -- (3 1 ) - -- (3 2 1) - -- (3 2 1 ) - -- (3 1 ) - --- (2 ) + -- (2 1 )
      36      24      36      72      192      48
+
      1      2 4      1      6      1      8
      -- (2 1 ) - --- (2 1 ) + --- (1 )
      96      144      576
Type: SymmetricPolynomial Fraction Integer
```

This is the number filled with a a b b c c d d.

```
cap(sf3221,complete 2**4)
3
Type: Fraction Integer
```

The configurations enumerated above are:

a a b	a a c	a a d
b c	b b	b b
c d	c d	c c
d	d	d

This is the number of tableaux filled with 1..8.

```
cap(sf3221, powerSum 1**8)
70
Type: Fraction Integer
```

The coefficient of  $x^n$  is the number of column strict reverse plane partitions of  $n$  of shape 3 2 2 1.

```
eval(Integers, sf3221)
9      10      11      12      13      14      15      16      17
x  + 3x  + 7x  + 14x  + 27x  + 47x  + 79x  + 126x  + 196x
+
18      19      20
294x  + 432x  + 0(x )
Type: UnivariateLaurentSeries(Fraction Integer,x,0)
```

The smallest is

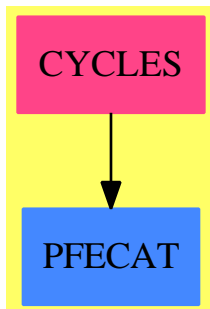

```
0 0 0
1 1
2 2
3
```

## 4.22.1 CycleIndicators (CYCLES)

**Exports:**

alternating	cap	complete	cup	cyclic
dihedral	elementary	eval	graphs	powerSum
SFunction	skewSFunction	wreath		

— package CYCLES CycleIndicators —

```

)abbrev package CYCLES CycleIndicators
++ Author: William H. Burge
++ Date Created: 1986
++ Date Last Updated: 11 Feb 1992
++ Keywords:Polya, Redfield, enumeration
++ Examples:
++ References: J.H.Redfield, 'The Theory of Group-Reduced Distributions',
++             American J. Math., 49 (1927) 433-455.
++             G.Polya, 'Kombinatorische Anzahlbestimmungen fur Gruppen,
++             Graphen und chemische Verbindungen', Acta Math. 68
++             (1937) 145-254.
++ Description:
++ Polya-Redfield enumeration by cycle indices.

```

CycleIndicators: Exports == Implementation where

```

I  ==> Integer
L  ==> List
B  ==> Boolean
SPOL ==> SymmetricPolynomial
PTN ==> Partition
RN  ==> Fraction Integer
FR  ==> Factored Integer
h  ==> complete
s  ==> powerSum
--a ==> elementary
alt ==> alternating
cyc ==> cyclic
dih ==> dihedral

```

```

ev == eval
Exports ==> with

complete: I -> SPOL RN
++\spad{complete n} is the \spad{n} th complete homogeneous
++ symmetric function expressed in terms of power sums.
++ Alternatively it is the cycle index of the symmetric
++ group of degree n.

powerSum: I -> SPOL RN
++\spad{powerSum n} is the \spad{n} th power sum symmetric
++ function.

elementary: I -> SPOL RN
++\spad{elementary n} is the \spad{n} th elementary symmetric
++ function expressed in terms of power sums.

-- s2h: I -> SPOL RN--s to h

alternating: I -> SPOL RN
++\spad{alternating n} is the cycle index of the
++ alternating group of degree n.

cyclic: I -> SPOL RN    --cyclic group
++\spad{cyclic n} is the cycle index of the
++ cyclic group of degree n.

dihedral: I -> SPOL RN    --dihedral group
++\spad{dihedral n} is the cycle index of the
++ dihedral group of degree n.

graphs: I -> SPOL RN
++\spad{graphs n} is the cycle index of the group induced on
++ the edges of a graph by applying the symmetric function to the
++ n nodes.

cap: (SPOL RN,SPOL RN) -> RN
++\spad{cap(s1,s2)}, introduced by Redfield,
++ is the scalar product of two cycle indices.

cup: (SPOL RN,SPOL RN) -> SPOL RN
++\spad{cup(s1,s2)}, introduced by Redfield,
++ is the scalar product of two cycle indices, in which the
++ power sums are retained to produce a cycle index.

eval: SPOL RN -> RN
++\spad{eval s} is the sum of the coefficients of a cycle index.

wreath: (SPOL RN,SPOL RN) -> SPOL RN
++\spad{wreath(s1,s2)} is the cycle index of the wreath product

```

```

++ of the two groups whose cycle indices are \spad{s1} and
++ \spad{s2}.

SFunction:L I -> SPOL RN
++\spad{SFunction(li)} is the S-function of the partition \spad{li}
++ expressed in terms of power sum symmetric functions.

skewSFunction:(L I,L I) -> SPOL RN
++\spad{skewSFunction(li1,li2)} is the S-function
++ of the partition difference \spad{li1 - li2}
++ expressed in terms of power sum symmetric functions.

— package DFINTTLS DefiniteIntegrationTools —

```
)abbrev package DFINTTLS DefiniteIntegrationTools
++ Author: Manuel Bronstein
++ Date Created: 15 April 1992
++ Date Last Updated: 24 February 1993
++ Description:
++ \spadtype{DefiniteIntegrationTools} provides common tools used
++ by the definite integration of both rational and elementary functions.

DefiniteIntegrationTools(R, F): Exports == Implementation where
```

```

R : Join(GcdDomain, OrderedSet, RetractableTo Integer,
        LinearlyExplicitRingOver Integer)
F : Join(TranscendentalFunctionCategory,
        AlgebraicallyClosedFunctionSpace R)

B ==> Boolean
Z ==> Integer
Q ==> Fraction Z
SE ==> Symbol
P ==> Polynomial R
RF ==> Fraction P
UP ==> SparseUnivariatePolynomial F
K ==> Kernel F
OFE ==> OrderedCompletion F
UPZ ==> SparseUnivariatePolynomial Z
UPQ ==> SparseUnivariatePolynomial Q
REC ==> Record(left:Q, right:Q)
REC2==> Record(endpoint:Q, dir:Z)
U ==> Union(fin:REC, halfinf:REC2, all:"all", failed:"failed")
IGNOR ==> "noPole"

Exports ==> with
  ignore?: String -> B
    ++ ignore?(s) is true if s is the string that tells the integrator
    ++ to assume that the function has no pole in the integration interval.
  computeInt: (K, F, OFE, OFE, B) -> Union(OFE, "failed")
    ++ computeInt(x, g, a, b, eval?) returns the integral of \spad{f} for x
    ++ between a and b, assuming that g is an indefinite integral of
    ++ \spad{f} and \spad{f} has no pole between a and b.
    ++ If \spad{eval?} is true, then \spad{g} can be evaluated safely
    ++ at \spad{a} and \spad{b}, provided that they are finite values.
    ++ Otherwise, limits must be computed.
  checkForZero: (P, SE, OFE, OFE, B) -> Union(B, "failed")
    ++ checkForZero(p, x, a, b, incl?) is true if p has a zero for x between
    ++ a and b, false otherwise, "failed" if this cannot be determined.
    ++ Check for a and b inclusive if incl? is true, exclusive otherwise.
  checkForZero: (UP, OFE, OFE, B) -> Union(B, "failed")
    ++ checkForZero(p, a, b, incl?) is true if p has a zero between
    ++ a and b, false otherwise, "failed" if this cannot be determined.
    ++ Check for a and b inclusive if incl? is true, exclusive otherwise.

blowUp: InfClsPoint -> List InfClsPoint

divisorAtDesingTree: (PolyRing,DesTree) -> DIVISOR
++ divisorAtDesingTree(f,tr) computes the local
++ divisor of f at a desingularisation tree tr of
++ a singular point.

adjunctionDivisor: DesTree -> DIVISOR
++ adjunctionDivisor(tr) compute the local
++ adjunction divisor of a desingularisation tree tr of
++ a singular point.

blowUpWithExcpDiv: DesTree -> Void -- DesTree

desingTreeAtPoint: (ProjPt,PolyRing) -> DesTree

```

```

++ desingTreeAtPoint(pt,pol) computes
++ the desingularisation tree at the point pt
++ on the curve defined by pol.
++ This function recursively compute the tree.

desingTree: PolyRing -> List DesTree
++ desingTree(pol) returns all the desingularisation
++ trees of all singular points on the curve
++ defined by pol.

fullParamInit: DesTree -> Void
++ fullParamInit(tr) initialize the local
++ parametrization at all places (leaves of tr),
++ computes the local exceptional divisor
++ at each infinytly close points in the tree.
++ This function is equivalent to the following called:
++ initParLocLeaves(tr)
++ initializeParamOfPlaces(tr)
++ blowUpWithExcpDiv(tr)

initParLocLeaves: DesTree -> Void
++ initParLocLeaves(tr) initialize the local
++ parametrization at simple points corresponding to
++ the leaves of tr.

initializeParamOfPlaces: DesTree -> Void
++ initParLocLeaves(tr) initialize the local
++ parametrization at places corresponding to
++ the leaves of tr.

initializeParamOfPlaces: (DesTree,List PolyRing) -> Void
++ initParLocLeaves(tr,listOfFnc) initialize
++ the local parametrization at places corresponding to
++ the leaves of tr according to the given
++ list of functions in listOfFnc.

genus: PolyRing -> NNI
++ genus(pol) computes the genus of the curve defined by pol.

genusNeg: PolyRing -> INT
++ genusNeg(pol) computes the "genus" of a curve
++ that may be not absolutly irreducible.
++ A "negative" genus means that
++ the curve is reducible !!.

genusTree: (NNI,List(DesTree)) -> NNI
++ genusTree(n,listOfTrees) computes the genus of a curve,
++ where n is the degree of a polynomial pol
++ defining the curve and listOfTrees is all
++ the desingularisation trees at all singular points

```

```

    ++ on the curve defined by pol.

inBetweenExcpDiv: DesTree -> DIVISOR

genusTreeNeg: (NNI,List(DesTree)) -> INT
  ++ genusTreeNeg(n,listOfTrees) computes the "genus"
  ++ of a curve that may be not absolutely irreducible,
  ++ where n is the degree of a polynomial pol
  ++ defining the curve and listOfTrees is all the
  ++ desingularisation trees at all singular points
  ++ on the curve defined by pol.
  ++ A "negative" genus means that
  ++ the curve is reducible !!.

### 5.4.1 DiophantineSolutionPackage (DIOSP)

#### Exports:

dioSolve

— package DIOSP DiophantineSolutionPackage —

```
)abbrev package DIOSP DiophantineSolutionPackage
++ Author: A. Fortenbacher
++ Date Created: 29 March 1991
++ Date Last Updated: 29 March 1991
++ Basic Operations: dioSolve
++ Related Constructors: Equation, Vector
++ Also See:
++ AMS Classifications:
++ Keywords: Diophantine equation, nonnegative solutions,
++   basis, depth-first-search
++ Reference:
++   M. Clausen, A. Fortenbacher: Efficient Solution of
++   Linear Diophantine Equations. in JSC (1989) 8, 201-216
++ Description:
++ Any solution of a homogeneous linear Diophantine equation
++ can be represented as a sum of minimal solutions, which
++ form a "basis" (a minimal solution cannot be represented
```

```

++ as a nontrivial sum of solutions)
++ in the case of an inhomogeneous linear Diophantine equation,
++ each solution is the sum of a inhomogeneous solution and
++ any number of homogeneous solutions
++ therefore, it suffices to compute two sets:\br
++ \tab{5}1. all minimal inhomogeneous solutions\br
++ \tab{5}2. all minimal homogeneous solutions\br
++ the algorithm implemented is a completion procedure, which
++ enumerates all solutions in a recursive depth-first-search
++ it can be seen as finding monotone paths in a graph
++ for more details see Reference

```

++ Related Constructors:
++ Also See:
++ AMS Classifications:
++ Keywords:
++ References:
++ Description:
++ This package provides operations which all take as arguments direct
++ products of elements of some type \spad{A} and functions from \spad{A}
++ to another type B. The operations all iterate over their vector argument
++ and either return a value of type B or a direct product over B.

DirectProductFunctions2(dim, A, B): Exports == Implementation where
  dim : NonNegativeInteger
  A, B: Type

DA ==> DirectProduct(dim, A)
DB ==> DirectProduct(dim, B)
VA ==> Vector A
VB ==> Vector B
O2 ==> FiniteLinearAggregateFunctions2(A, VA, B, VB)

Exports ==> with
  scan : ((A, B) -> B, DA, B) -> DB
    ++ scan(func,vec,ident) creates a new vector whose elements are
    ++ the result of applying reduce to the binary function func,
    ++ increasing initial subsequences of the vector vec,
    ++ and the element ident.
  reduce : ((A, B) -> B, DA, B) -> B
    ++ reduce(func,vec,ident) combines the elements in vec using the
    ++ binary function func. Argument ident is returned if the vector is empty.
  map : (A -> B, DA) -> DB
    ++ map(f, v) applies the function f to every element of the vector v
    ++ producing a new vector containing the values.

Implementation ==> add
  import FiniteLinearAggregateFunctions2(A, VA, B, VB)

  map(f, v) == directProduct map(f, v::VA)
  scan(f, v, b) == directProduct scan(f, v::VA, b)

C == with
  factor      :      FP      -> Factored FP
  ++ factor(p) produces the complete factorization of the polynomial p.
  factorSquareFree :      FP      -> Factored FP
  ++ factorSquareFree(p) produces the complete factorization of the
  ++ square free polynomial p.
  distdfact    : (FP, Boolean) -> FinalFact
  ++ distdfact(p, sqfrflag) produces the complete factorization
  ++ of the polynomial p returning an internal data structure.
  ++ If argument sqfrflag is true, the polynomial is assumed square free.
  separateDegrees :      FP      -> List fact
  ++ separateDegrees(p) splits the square free polynomial p into
  ++ factors each of which is a product of irreducibles of the
  ++ same degree.
  separateFactors : List fact -> List FP
  ++ separateFactors(lfact) takes the list produced by separateDegrees
  ++ and produces the complete list of factors.
  exptMod      : (FP, NNI, FP) -> FP
  ++ exptMod(u,k,v) raises the polynomial u to the kth power
  ++ modulo the polynomial v.
  trace2PowMod : (FP, NNI, FP) -> FP
  ++ trace2PowMod(u,k,v) produces the sum of u**(2**i) for i running

```

```

    ++ from 1 to k all computed modulo the polynomial v.
tracePowMod      : (FP,NNI,FP)  -> FP
    ++ tracePowMod(u,k,v) produces the sum of \spad{u**(q**i)}
    ++ for i running and q= size F
irreducible?     : FP          -> Boolean
    ++ irreducible?(p) tests whether the polynomial p is irreducible.

```

```

## 5.9 package DFSFUN DoubleFloatSpecialFunctions

The special functions in this section are developed as special cases but can all be expressed in terms of generalized hypergeometric functions  ${}_pF_q$  or its generalization, the Meijer G function. [?, ?] The long term plan is to reimplement these functions using the generalized version.

The formula used will agree with the Table of the Fresnel Integral by Pearcey (1959) to 6 decimal places up to an argument of about 35.0. After that the summation gets slowly worse, agreeing to only 2 digits at about 45.0.

++ Gamma(x) is the Euler gamma function, \spad{Gamma(x)}, defined by
++ \spad{Gamma(x) = integrate(t^(x-1)*exp(-t), t=0..%infinity)}.
Gamma: C -> C
++ Gamma(x) is the Euler gamma function, \spad{Gamma(x)}, defined by
++ \spad{Gamma(x) = integrate(t^(x-1)*exp(-t), t=0..%infinity)}.

E1: R -> OPR
++ E1(x) is the Exponential Integral function
++ The current implementation is a piecewise approximation
++ involving one poly from -4..4 and a second poly for x > 4

En: (PI,R) -> OPR
++ En(n,x) is the nth Exponential Integral Function

Ei: (OPR) -> OPR
++ Ei is the Exponential Integral function
++ This is computed using a 6 part piecewise approximation.
++ DoubleFloat can only preserve about 16 digits but the
++ Chebyshev approximation used can give 30 digits.

Ei1: (OPR) -> OPR
++ Ei1 is the first approximation of Ei where the result is
++ x*%e^-x*Ei(x) from -infinity to -10 (preserves digits)

Ei2: (OPR) -> OPR
++ Ei2 is the first approximation of Ei where the result is
++ x*%e^-x*Ei(x) from -10 to -4 (preserves digits)

Ei3: (OPR) -> OPR
++ Ei3 is the first approximation of Ei where the result is
++ (Ei(x)-log |x| - gamma)/x from -4 to 4 (preserves digits)

Ei4: (OPR) -> OPR
++ Ei4 is the first approximation of Ei where the result is
++ x*%e^-x*Ei(x) from 4 to 12 (preserves digits)

Ei5: (OPR) -> OPR
++ Ei5 is the first approximation of Ei where the result is
++ x*%e^-x*Ei(x) from 12 to 32 (preserves digits)

Ei6: (OPR) -> OPR
++ Ei6 is the first approximation of Ei where the result is
++ x*%e^-x*Ei(x) from 32 to infinity (preserves digits)

Beta: (R, R) -> R
++ Beta(x, y) is the Euler beta function, \spad{B(x,y)}, defined by
++ \spad{Beta(x,y) = integrate(t^(x-1)*(1-t)^(y-1), t=0..1)}.
++ This is related to \spad{Gamma(x)} by
++ \spad{Beta(x,y) = Gamma(x)*Gamma(y) / Gamma(x + y)}.
Beta: (C, C) -> C

```

```

++ Beta(x, y) is the Euler beta function, \spad{B(x,y)}, defined by
++ \spad{Beta(x,y) = integrate(t^(x-1)*(1-t)^(y-1), t=0..1)}.
++ This is related to \spad{Gamma(x)} by
++ \spad{Beta(x,y) = Gamma(x)*Gamma(y) / Gamma(x + y)}.

logGamma: R -> R
++ logGamma(x) is the natural log of \spad{Gamma(x)}.
++ This can often be computed even if \spad{Gamma(x)} cannot.
logGamma: C -> C
++ logGamma(x) is the natural log of \spad{Gamma(x)}.
++ This can often be computed even if \spad{Gamma(x)} cannot.

digamma: R -> R
++ digamma(x) is the function, \spad{psi(x)}, defined by
++ \spad{psi(x) = Gamma'(x)/Gamma(x)}.
digamma: C -> C
++ digamma(x) is the function, \spad{psi(x)}, defined by
++ \spad{psi(x) = Gamma'(x)/Gamma(x)}.

polygamma: (NNI, R) -> R
++ polygamma(n, x) is the n-th derivative of \spad{digamma(x)}.
polygamma: (NNI, C) -> C
++ polygamma(n, x) is the n-th derivative of \spad{digamma(x)}.

besselJ: (R,R) -> R
++ besselJ(v,x) is the Bessel function of the first kind,
++ \spad{J(v,x)}.
++ This function satisfies the differential equation:
++ \spad{x^2 w''(x) + x w'(x) + (x^2-v^2)w(x) = 0}.
besselJ: (C,C) -> C
++ besselJ(v,x) is the Bessel function of the first kind,
++ \spad{J(v,x)}.
++ This function satisfies the differential equation:
++ \spad{x^2 w''(x) + x w'(x) + (x^2-v^2)w(x) = 0}.

besselY: (R, R) -> R
++ besselY(v,x) is the Bessel function of the second kind,
++ \spad{Y(v,x)}.
++ This function satisfies the differential equation:
++ \spad{x^2 w''(x) + x w'(x) + (x^2-v^2)w(x) = 0}.
++ Note that the default implementation uses the relation
++ \spad{Y(v,x) = (J(v,x) cos(v*pi) - J(-v,x))/sin(v*pi)}
++ so is not valid for integer values of v.
besselY: (C, C) -> C
++ besselY(v,x) is the Bessel function of the second kind,
++ \spad{Y(v,x)}.
++ This function satisfies the differential equation:
++ \spad{x^2 w''(x) + x w'(x) + (x^2-v^2)w(x) = 0}.
++ Note that the default implementation uses the relation
++ \spad{Y(v,x) = (J(v,x) cos(v*pi) - J(-v,x))/sin(v*pi)}

```

++ so is not valid for integer values of v.

```

besselI: (R,R) -> R
++ besselI(v,x) is the modified Bessel function of the first kind,
++ \spad{I(v,x)}.
++ This function satisfies the differential equation:
++ \spad{x^2 w''(x) + x w'(x) - (x^2+v^2)w(x) = 0}.
besselI: (C,C) -> C
++ besselI(v,x) is the modified Bessel function of the first kind,
++ \spad{I(v,x)}.
++ This function satisfies the differential equation:
++ \spad{x^2 w''(x) + x w'(x) - (x^2+v^2)w(x) = 0}.

besselK: (R, R) -> R
++ besselK(v,x) is the modified Bessel function of the second kind,
++ \spad{K(v,x)}.
++ This function satisfies the differential equation:
++ \spad{x^2 w''(x) + x w'(x) - (x^2+v^2)w(x) = 0}.
++ Note that the default implementation uses the relation
++ \spad{K(v,x) = %pi/2*(I(-v,x) - I(v,x))/sin(v*%pi)}.
++ so is not valid for integer values of v.
besselK: (C, C) -> C
++ besselK(v,x) is the modified Bessel function of the second kind,
++ \spad{K(v,x)}.
++ This function satisfies the differential equation:
++ \spad{x^2 w''(x) + x w'(x) - (x^2+v^2)w(x) = 0}.

## 5.9.2 The Exponential Integral

### The E1 function

(Quoted from Segletes[?]):

A number of useful integrals exist for which no exact solutions have been found. In other cases, an exact solution, if found, may be impractical to utilize over the complete domain of the function because of precision limitations associated with what usually ends up as a series solution to the challenging integral. For many of these integrals, tabulated values may be published in various mathematical handbooks and articles. In some handbooks, fits (usually piecewise) also are offered. In some cases, an application may be forced to resort to numerical integration in order to acquire the integrated function. In this context, compact (*i.e.* not piecewise) analytical fits to some of these problematic integrals, accurate to within a small fraction of the numerically integrated value, serve as a useful tool to applications requiring the results of the integration, especially when the integration is required numerous times throughout the course of the application. Furthermore, the ability and methodology to develop intelligent fits, in contrast to the more traditional “brute force” fits, provide the means to minimize parameters and maximize accuracy when tackling some of these difficult functions. The exponential integral will be used as an opportunity to both demonstrate a methodology for intelligent fitting as well as for providing an accurate, compact, analytical fit to the exponential integral.

The exponential integral is a useful class of functions that arise in a variety of applications [...]. The real branch of the family of exponential integrals may be defined as

$$E_n(x) = x^{n-1} \int_x^\infty \frac{e^{-t}}{t^n} dt \quad (5.1)$$

where  $n$ , a positive integer, denotes the specific member of the exponential integral family. The argument of the exponential integral, rather than expressing a lower limit of integration as in (1), may be thought of as describing the exponential decay constant, as given in this equivalent (and perhaps more popular) definition of the integral:

$$E_n(x) = \int_1^\infty \frac{e^{-xt}}{t^n} dt \quad (5.2)$$

Integration by parts permits any member of the exponential integral family to be converted to an adjacent member of the family, by way of

$$\int_x^\infty \frac{e^{-t}}{t^{n+1}} dt = \frac{1}{n} \left( \frac{e^{-x}}{x^n} - \int_x^\infty \frac{e^{-t}}{t^n} dt \right) \quad (5.3)$$

expressable in terms of  $E_n$  as

$$E_{n+1}(x) = \frac{1}{n} [e^{-x} - xE_n(x)] \quad (n = 1, 2, 3) \quad (5.4)$$

Through recursive employment of this equation, all members of the exponential integral family may be analytically related. However, this technique only allows for the transformation of one integral into another. There remains the problem of evaluating  $E_1(x)$ . There is an exact solution to the integral of  $(e^{-t}/t)$ , appearing in a number of mathematical references [?, ?] which is obtainable by expanding the exponential into a power series and integrating term by term. That exact solution, which is convergent, may be used to specify  $E_1(x)$  as

$$E_1(x) = -\gamma - \ln(x) + \frac{x}{1!} - \frac{x^2}{2 \cdot 2!} + \frac{x^3}{3 \cdot 3!} - \dots \quad (5.5)$$

Euler's constant,  $\gamma$ , equal to  $0.57721\dots$ , arises when the power series expansion for  $(e^{-t}/t)$  is integrated and evaluated at its upper limit, as  $x \rightarrow \infty$  [?].

Employing eqn (5), however, to evaluate  $E_1(x)$  is problematic for finite  $x$  significantly larger than unity. One may well ask of the need to evaluate the exponential integral for large  $x$ , since the function to be integrated drops off so rapidly that the integral is surely a very flat function. Such reasoning is true when comparing the integrand at large  $x$  to that at small  $x$ . However, the definition of eqn (1) has as its upper limit not a small value of  $x$ , but rather that of  $\infty$ . Therefore, the actual values for  $E_n(x)$  are extremely small numbers for large values of  $x$ . Thus, it is not sufficient merely to select enough terms of eqn (5) to evaluate the integral to within a value of, for example  $\pm 0.0001$  because the actual integral value for large  $x$  would be smaller than this arbitrary tolerance. To draw an analogy, it would be like saying that it is good enough to approximate  $e^{-x}$  as 0.0 for  $x > 10$ , since its actual value

is within 0.0001 of zero. For some applications, such an approximation may be warranted. In general, though, such an approximation is mathematically unacceptable. Worse yet, as seen from eqns (1) and (2), the need to evaluate the exponential integral for large arguments can arise in real-world problems from either a large integration limit or a large value of an exponential decay constant. Thus, the need to evaluate exponential integrals for large values of the argument is established. It is here that the practical problems with the evaluation of eqn (5) become manifest.

First, the number of terms,  $N$ , required to achieve convergence rises rapidly with increasing  $x$ , making the summation an inefficient tool, even when expressed as a recursion relation (for three digits of accuracy,  $N$  is observed to vary roughly as  $9 + 1.6x$ , for  $1 < x < 7$ ). More important, however, is the fact that, for calculations of finite precision, the accuracy of the complete summation will be governed by the individual term of greatest magnitude. The source of the problem is that as  $x$  is increased, the total summation decreases in magnitude more rapidly than a decaying exponential, while at the same time, the largest individual term in the series is observed to grow rapidly with increasing  $x$  ( $10^1$  for  $x = 7$ ,  $10^2$  for  $x = 10$ ,  $10^3$  for  $x = 13$ , etc.). The magnitude of this largest individual term consumes the available precision and, as a result, leaves little or none left for the ever-diminishing net sum that constitutes the desired integral.

Literally, the use of eqn (5), even with (32-bit) double precision, does not permit the exponential integral to be evaluated to three places for  $x > 14$  in any case, and with the situation worsening for lesser precision. For these reasons, the use of eqn (5) to evaluate the exponential integral numerically for large  $x$  is wholly unsuitable.

$$E_1(x) = e^{-x} \cdot \frac{1}{x + \frac{1}{1 + \frac{1}{x + \frac{2}{1 + \frac{2}{x + \dots}}}}} \quad (5.6)$$

But as  $x$  becomes smaller, the number of terms required for convergence rises quickly. Similar arguments apply for the use of an asymptotic expansion for  $E_1$ , which also converges for large  $x$ . As such, the more typical approach employed by handbooks is that of a fit. While some steps are taken to make the fits intelligent (e.g., transformation of variables), the fits are all piecewise over the domain of the integral.

Cody and Thatcher [?] performed what is perhaps the definitive work, with the use of Chebyshev[?, ?] approximations to the exponential integral  $E_1$ . Like others, they fit the integral over a piecewise series of subdomains (three in their case) and provide the fitting parameters necessary to evaluate the function to various required precisions, down to relative errors of  $10^{-20}$ . One of the problems with piecewise fitting over two or more subdomains is that functional value and derivatives of the spliced fits will not, in general, match at the domain transition point, unless special accommodations are made. This sort of discontinuity in functional value and/or slope, curvature, etc., may cause difficulties for some numerical algorithms operating upon the fitted function. Numerical splicing/smoothing algorithms aimed at eliminating discontinuities in the value and/or derivatives of a piecewise fit are not,

in general, computationally insignificant. Problems associated with piecewise splicing of fits may also be obviated by obtaining an accurate enough fit, such that the error is on the order of magnitude of the limiting machine precision. This alternative, however, requires the use of additional fitting parameters to acquire the improved precision. Thus, regardless of approach, the desire to eliminate discontinuities in the function and its derivatives, between piecewise splices, requires extra computational effort. One final benefit to be had by avoiding the use of piecewise fits is the concomitant avoidance of conditional (*i.e.*, IF...THEN) programming statements in the coding of the routine. The use of conditional statements can preclude maximum computing efficiency on certain parallel computing architectures.

Segletes constructs an analytic, non-piecewise fit to the Exponential Integral but the precision is on the order of 4 decimal places and is not sufficient to compare against the Abramowitz and Stegun Handbook.

Instead we have chosen to use a two piece fitting function based on the Chebyshev polynomial for computing  $E_1$ . This agrees with the handbook values to almost the last published digit. See the `e1.input` pamphlet for regression testing against the handbook tables.

### E1:R→OPR

The special function E1 below was originally derived from a function written by T.Haavie as the `expint.c` function in the Numlibc library by Lars Erik Lund. Haavie approximates the E1 function by two Chebyshev polynomials. For the range  $-4 < x < 4$  the Chebyshev coefficients are:

```
7.8737715392882774, -8.0314874286705335, 3.8797325768522250,
-1.6042971072992259, 0.5630905453891458, -0.1704423017433357,
0.0452099390015415, -0.0106538986439085, 0.0022562638123478,

0.00000000000007691, -0.00000000000002070, 0.0000000000000573,
-0.00000000000000163, 0.00000000000000047, -0.00000000000000014,
0.00000000000000004, -0.00000000000000001
```

I've rewritten the polynomial to use precomputed coefficients that take into account the scaling used by Haavie. I've also rewritten the polynomial using Horner's method so the large powers of  $x$  are only computed once.

The result can be either a double float or, or if the argument is zero, infinity. Thus we need to extend the result to be a one-point completion to include infinity.

### 5.9.3 $\text{En}:(\text{PI},\text{R})\rightarrow\text{OPR}$

The  $E_n$  function is computed using the recurrence relation:

$$E_{n+1}(z) = \frac{1}{n} (e^{-z} - zE_n(z)) \quad (n = 1, 2, 3, \dots)$$

The base case of the recursion depends on E1 above.

The formula is 5.1.14 in Abramowitz and Stegun, 1965, p229[?].

— package DFSFUN DoubleFloatSpecialFunctions —

```

En(n:PI,x:R):OPR ==

### 5.9.4 The Ei Function

This function is based on Kin L. Lee's work[?]. See also [?].

#### Abstract

The exponential integral  $\text{Ei}(x)$  is evaluated via Chebyshev series expansion of its associated functions to achieve high relative accuracy throughout the entire real line. The Chebyshev coefficients for these functions are given to 30 significant digits. Clenshaw's[?] method is modified to furnish an efficient procedure for the accurate solution of linear systems having near-triangular coefficient matrices.

## Introduction

The evaluation of the exponential integral

$$Ei(x) = \int_{-\infty}^x \frac{e^u}{u} du = -E_1(-x), x \neq 0 \quad (5.7)$$

is usually based on the value of its associated functions, for example,  $xe^{-x}Ei(x)$ . High accuracy tabulations of integral (1) by means of Taylor series techniques are given by Harris [?] and Miller and Hurst [?]. The evaluation of  $Ei(x)$  for  $-4 \leq x \leq \infty$  by means of Chebyshev series is provided by Clenshaw [?] to have the absolute accuracy of 20 decimal places. The evaluation of the same integral (1) by rational approximation of its associated functions is furnished by Cody and Thacher [?, ?] for  $-\infty < x < \infty$ , and has the relative accuracy of 17 significant figures.

The approximation of Cody and Thacher from the point of view of efficient function evaluation are preferable to those of Clenshaw. However, the accuracy of the latter's procedure, unlike those of the former, is not limited by the accuracy or the availability of a master function, which is a means of explicitly evaluating the function in question.

In this paper  $Ei(x)$  (or equivalently  $-E_1(-x)$ ) for the entire real line is evaluated via Chebyshev series expansion of its associated functions that are accurate to 30 significant figures by a modification of Clenshaw's procedure. To verify the accuracy of the several Chebyshev series, values of the associated functions were checked against those computed by Taylor series and those of Murnaghan and Wrench [?] (see Remarks on Convergence and Accuracy).

Although for most purposes fewer than 30 figures of accuracy are required, such high accuracy is desirable for the following reasons. In order to further reduce the number of arithmetical operations in the evaluation of a function, the Chebyshev series in question can either be converted into a rational function or rearranged into an ordinary polynomial. Since several figures may be lost in either of these procedures, it is necessary to provide the Chebyshev series with a sufficient number of figures to achieve the desired accuracy. Furthermore, general function approximation routines, such as those used for minimax rational function approximations, require the explicit evaluation of the function to be approximated. To take account of the errors committed by these routines, the function values must have an accuracy higher than the approximation to be determined. Consequently, high-precision results are useful as a master function for finding approximations for (or involving)  $Ei(x)$  (e.g. [?, ?]) where prescribed accuracy is less than 30 figures.

## Discussion

It is proposed here to provide for the evaluation of  $Ei(x)$  by obtaining Chebyshev coefficients for the associated functions given by table 1.

**Table 1:** Associated Functions of  $Ei(x)$  and their ranges of Chebyshev Series Expansions

	Associated function	Range of expansion
Ei1	$xe^{-x} Ei(x)$	$-\infty < x \leq -10$
Ei2	$xe^{-x} Ei(x)$	$-10 \leq x \leq -4$
Ei3	$\frac{Ei(x) - \log x  - \gamma}{x}$	$-4 \leq x \leq d42$
Ei4	$xe^{-x} Ei(x)$	$4 \leq x \leq 12$
Ei5	$xe^{-x} Ei(x)$	$12 \leq x \leq 32$
Ei6	$xe^{-x} Ei(x)$	$32 \leq x < \infty$

( $\gamma = 0.5772156649\dots$  is Euler's constant.)

— package DFSFUN DoubleFloatSpecialFunctions —

```

Ei(y:OPR):OPR ==
  infinite? y => 1
  x:R:=retract(y)
  x < -10.0::R =>
    ei:R:=retract(Ei1(y))
    (ei/(x*exp(-x)))::OPR
  x < -4.0::R =>
    ei:R:=retract(Ei2(y))
    (ei/(x*exp(-x)))::OPR
  x < 4.0::R =>
    ei3:R:=retract(Ei3(y))
    gamma:R:=0.577215664901532860606512090082::R
    (ei3*x+log(abs(x))+gamma)::OPR
  x < 12.0::R =>
    ei:R:=retract(Ei4(y))
    (ei/(x*exp(-x)))::OPR
  x < 32.0::R =>
    ei:R:=retract(Ei5(y))
    (ei/(x*exp(-x)))::OPR
  ei:R:=retract(Ei6(y))
  (ei/(x*exp(-x)))::OPR

```

Note that the functions  $[Ei(x) - \log|x| - \gamma]/x$  and  $xe^{-x} Ei(x)$  have the limiting values of unity at the origin and at infinity, respectively, and that the range of the associated function values is close to unity (see table 4). This makes for the evaluation of the associated functions over the indicated ranges in table 1 (and thus  $Ei(x)$  over the entire real line) with high relative accuracy by means of the Chebyshev series. The reason for this will become apparent later.

Some remarks about the choice of the intervals of expansion for the several Chebyshev series are in order here. The partition of the real line indicated by table 1 is chosen to allow for the approximation of the associated functions with a maximum error of  $0.5 \times 10^{-30}$  by polynomials of degree  $< 50$ . The real line has also been partitioned with the objective of providing the interval about zero with the lowest degree of polynomial approximation of the six intervals. This should compensate for the computation of  $\log|x|$  required in the evaluation of  $Ei(x)$  over that interval. The ranges  $-\infty < x \leq -4$  and  $4 \leq x < \infty$  are partitioned into

2 and 3 intervals, respectively, to provide approximations to  $xe^{-x}Ei(x)$  by polynomials of about the same degree.

### Expansions in Chebyshev Series

Let  $\phi(t)$  be a differentiable function defined on  $[-1,1]$ . To facilitate discussion, denote its Chebyshev series and that of its derivative by

$$\phi(t) = \sum_{k=0}^{\infty} {}'A_k^{(0)} T_k(t) \quad \phi'(t) = \sum_{k=0}^{\infty} {}'A_k^{(1)} T_k(t) \quad (5.8)$$

where  $T_k(t)$  are Chebyshev polynomials defined by

$$T_k(t) = \cos(k \arccos t), \quad -1 \leq t \leq 1 \quad (5.9)$$

(A prime over a summation sign indicates that the first term is to be halved.)

If  $\phi(t)$  and  $\phi'(t)$  are continuous, the Chebyshev coefficients  $A_k^{(0)}$  and  $A_k^{(1)}$  can be obtained analytically (if possible) or by numerical quadrature. However, since each function in table 1 satisfies a linear differential equation with polynomial coefficients, the Chebyshev coefficients can be more readily evaluated by the method of Clenshaw [?].

There are several variations of Clenshaw's procedure (see, e.g. [?]), but for high-precision computation, where multiple precision arithmetic is employed, we find his original procedure easiest to implement. However, straightforward application of it may result in a loss of accuracy if the trial solutions selected are not sufficiently independent. How the difficulty is overcome will be pointed out subsequently.

### The function $xe^{-x}Ei(x)$ on the Finite Interval

We consider first the Chebyshev series expansion of

$$f(x) = xe^{-x}Ei(x), \quad (a \leq x \leq b) \quad (5.10)$$

with  $x \neq 0$ . One can easily verify that after the change of variables

$$x = [(b-a)T + a + b]/2, \quad (-1 \leq t \leq 1) \quad (5.11)$$

the function

$$\phi(t) = f\left[\frac{(b-a)t + a + b}{2}\right] = f(x) \quad (5.12)$$

satisfies the differential equation

$$2(pt + q)\phi'(t) + p(pt + q - 2)\phi(t) = p(pt + q) \quad (5.13)$$

with<sup>1</sup>

$$\phi(-1) = ae^{-a}Ei(a) \quad (5.14)$$

---

<sup>1</sup>The value of  $Ei(a)$  may be evaluated by means of the Taylor series. In this report  $Ei(a)$  is computed by first finding the Chebyshev series approximation to  $[Ei(x) - \log|x| - \gamma]/x$  to get  $Ei(a)$ . The quantities  $e^a$  and  $\log|a|$  for integral values of  $a$  may be found in existing tables

where  $p = b - a$  and  $q = b + a$ . Replacing  $\phi(t)$  and  $\phi'(t)$  in equations 7 by their Chebyshev series, we obtain

$$\sum_{k=0}^{\infty} '(-1)^k A_k^{(0)} = \phi(-1) \quad (5.15)$$

$$2 \sum_{k=0}^{\infty} 'A_k^{(1)}(pt+q)T_k(t) + p \sum_{k=0}^{\infty} 'A_k^{(0)}(pt+q-2)T_k(t) = p(pt+q) \quad (5.16)$$

It can be demonstrated that if  $B_k$  are the Chebyshev coefficients of a function  $\Psi(t)$ , then  $C_k$ , the Chebyshev coefficients of  $t^r \Psi(t)$  for positive integers  $r$ , are given by [?]

$$C_k = 2^{-r} \sum_{i=0}^r \binom{r}{i} B_{|k-r+2i|} \quad (5.17)$$

Consequently, the left member of equation 15 can be rearranged into a single series involving  $T_k(t)$ . The comparison of the coefficients of  $T_k(t)$  that yields the infinite system of equations

$$\left. \begin{aligned} & \sum_{k=0}^{\infty} '(-1)^k A_k^{(0)} = \phi(-1) \\ & 2pA_{|k-1|}^{(1)} + 4qA_k^{(1)} + 2pA_{k+1}^{(1)} + p^2A_{|k-1|}^{(0)} + 2p(q-2)A_k^{(0)} + p^2A_{k+1}^{(0)} \\ & = \begin{cases} 4pq & , \quad k=0 \\ 2p^2 & , \quad k=1 \\ 0 & , \quad k=2,3,\dots \end{cases} \end{aligned} \right\} \quad (5.18)$$

The relation [?]

$$2kA_k^{(0)} = A_{k-1}^{(1)} - A_{k+1}^{(1)} \quad (5.19)$$

can be used to reduce equation 18 to a system of equations involving only  $A_k^{(0)}$ . Thus, replacing  $k$  of equations 18 by  $k+2$  and subtracting the resulting equation from equations 18, we have, by means of equation 19, the system of equations

$$\left. \begin{aligned} & \sum_{k=0}^{\infty} '(-1)^k A_k^{(0)} = \phi(-1) \\ & 2p(q-2)A_0 + (8q+p^2)A_1 + 2p(6-q)A_2 - p^2A_3 = 4pq \\ & p^2A_{k-1} + 2p(2k+q-2)A_k + 8q(k+1)A_{k+1} + 2p(2k-q+6)A_{k+2} - p^2A_{k+3} \\ & = \begin{cases} 2p^2 & , \quad k=1 \\ 0 & , \quad k=2,3,\dots \end{cases} \end{aligned} \right\} \quad (5.20)$$

The superscript of  $A_k^{(0)}$  is dropped for simplicity. In order to solve the infinite system 20, Clenshaw [?] essentially considered the required solution as the limiting solution of the

sequence of truncated systems consisting of the first  $M + 1$  equations of the same system, that is, the solution of the system

$$\sum_{k=0}^M (-1)^k A_k = \phi(-1) \quad (5.21)$$

$$\left. \begin{aligned} &2p(q-2)A_0 + (8q+p^2)A_1 + 2p(q-6)A_2 - p^2A_3 = 4pq \\ &p^2A_{k-1} + 2p(2k+q-2)A_k + 8q(k+1)A_{k+1} + 2p(2k-q+6)A_{k+2} - p^2A_{k+3} \\ &= \begin{cases} 2p^2 & , \quad k=1 \\ 0 & , \quad k=2,3,\dots,M-3 \end{cases} \\ &p^2A_{M-3} + 2p(2M+q-6)A_{M-2} + 8q(M-1)A_{M-1} + 2p(2M+4-q)A_M = 0 \\ &p^2A_{M-2} + 2p(2M+q-4)A_{M-1} + 8qMA_M = 0 \end{aligned} \right\} \quad (5.22)$$

where  $A_k$  is assumed to vanish for  $K \geq M+1$ . To solve system (21,22,23) consider first the subsystem 23 consisting of  $M-2$  equations in  $M$  unknowns. Here use is made of the fact that the subsystem 23 is satisfied by

$$A_k = c_1\alpha_k + c_2\beta_k + \gamma_k \quad (k=0,1,2,\dots) \quad (5.24)$$

for arbitrary constants  $c_1$  and  $c_2$ , where  $\gamma_k$  is a particular solution of 23 and where  $\alpha_k$  and  $\beta_k$  are two independent solutions of the homogeneous equations (23 with  $2p^2$  deleted) of the same subsystem. Hence, if  $\alpha_k$ ,  $\beta_k$ , and  $\gamma_k$  are available, the solution of system (21,22,23) reduces to the determinant of  $c_1$  and  $c_2$  from equations 21 and 22.

To solve equations (21,22,23), we note that

$$\gamma_0 = 2, \quad \gamma_k = 0, \quad \text{for } k=1(1)M \quad (5.25)$$

is obviously a particular solution of equation 23. The two independent solutions  $\gamma_k$  and  $\beta_k$  of the homogeneous equations of the same subsystem can be generated in turn by backward recurrence if we set

$$\text{and} \quad \left. \begin{aligned} &\alpha_{M-1} = 0, \quad \alpha_M = 1 \\ &\beta_{M-1} = 1, \quad \beta_M = 0 \end{aligned} \right\} \quad (5.26)$$

or choose any  $\alpha_{M-1}$ ,  $\alpha_M$ , and  $\beta_{M-1}$ ,  $\beta_M$  for which  $\alpha_{M-1}\beta_M - \alpha_M\beta_{M-1} \neq 0$ . The arbitrary constants  $c_1$  and  $c_2$  are determined, and consequently the solution of equations (21,22,23) if equation 24 is substituted into equation 21 and 22 and the resulting equations

$$c_1R(\alpha) + c_2R(\beta) = \phi(-1) - 1 \quad (5.27)$$

$$c_1S(\alpha) + c_2S(\beta) = 8p \quad (5.28)$$

are solved as two equations in two unknowns. The terms  $R(\alpha)$  and  $S(\alpha)$  are equal, respectively, to the left members of equations 21 and 22 corresponding to solution  $\alpha_k$ . (The identical designation holds for  $R(\beta)$  and  $S(\beta)$ .)

The quantities  $\alpha_k$  and  $\beta_k$  are known as trial solutions in reference [?]. Clenshaw has pointed out that if  $\alpha_k$  and  $\beta_k$  are not sufficiently independent, loss of significance will occur in the formation of the linear combination 24, with consequent loss of accuracy. Clenshaw suggested the Gauss-Seidel iteration procedure to improve the accuracy of the solution. However, this requires the application of an additional computing procedure and may prove to be extremely slow. A simpler procedure which does not alter the basic computing scheme given above is proposed here. The loss of accuracy can effectively be regained if we first generate a third trial solution  $\delta_k$  ( $k=0,1,\dots,M$ ), where  $\delta_{M-1}$  and  $\delta_M$  are equal to  $c_1\alpha_{M-1} + c_2\beta_{M-1}$  and  $c_1\alpha_M + c_2\beta_M$ , respectively, and where  $\delta_k$  ( $k=M-2,M-3,\dots,0$ ) is determined using backward recurrence as before by means of equation 23. Then either  $\alpha_k$  or  $\beta_k$  is replaced by  $\delta_k$  and a new set of  $c_1$  and  $c_2$  is determined by equations 27 and 28. Such a procedure can be repeated until the required accuracy is reached. However, only one application of it was necessary in the computation of the coefficients of this report.

As an example, consider the case for  $4 \leq x \leq 12$  with  $M = 15$ . The right member of equation 27 and of equation 28 assume, respectively, the values of 0.43820800 and 64. The trial solutions  $\alpha_k$  and  $\beta_k$  generated with  $\alpha_{14} = 8$ ,  $\alpha_{15} = 9$  and  $\beta_{14} = 7$ ,  $\beta_{15} = 8$  are certainly independent, since  $\alpha_{14}\beta_{15} - \alpha_{15}\beta_{14} = 1 \neq 0$ . A check of table 2 shows that equations 27 and 28 have, respectively, the residuals of  $-0.137 \times 10^{-4}$  and  $-0.976 \times 10^{-3}$ . The same table also shows that  $c_1\alpha_k$  is opposite in sign but nearly equal in magnitude to  $c_2\beta_k$ . Cancellations in the formation of the linear combination 24 causes a loss of significance of 2 to 6 figures in the computed  $A_k$ . In the second iteration, where a new set of  $\beta_k$  is generated replacing  $\beta_{14}$  and  $\beta_{15}$ , respectively, by  $c_1\alpha_{14} + c_2\beta_{14}$  and  $c_1\alpha_{15} + c_2\beta_{15}$  of the first iteration, the new  $c_1\alpha_k$  and  $c_2\beta_k$  differed from 2 to 5 orders of magnitude. Consequently, no cancellation of significant figures in the computation of  $A_k$  occurred. Notice that equations 27 and 28 are now satisfied exactly. Further note that the new  $c_1$  and  $c_2$  are near zero and unity, respectively, for the reason that if equations 21, 22, and 23 are satisfied by equation 24 exactly in the first iteration, the new  $c_1$  and  $c_2$  should have the precise values zero and 1, respectively. The results of the third iteration show that the  $A_k$  of the second iteration are already accurate to eight decimal places, since the  $A_k$  in the two iterations differ in less than  $0.5 \times 10^{-8}$ . Notice that for the third iteration, equations 27 and 28 are also satisfied exactly and that  $c_1 = 1$  and  $c_2 = 0$  (relative to 8 places of accuracy).

$$c_1 S(\alpha) + c_2 S(\beta) - 0.64000000E\ 00 = 0.0$$

It is worth noting that the coefficient matrix of system (21,22,23) yields an upper triangular matrix of order  $M - 1$  after the deletion of the first two rows and the last two columns. Consequently, the procedure of this section is applicable to any linear system having this property. As a matter of fact, the same procedure can be generalized to solve linear systems having coefficient matrices of order  $N$ , the deletion of whose first  $r$  ( $r < N$ ) rows and last  $r$  columns yields upper triangular matrices of order  $N - r$ .

**The Function**  $(1/x)[Ei(x) - \log|x| - \gamma]$

Let

$$f(x) = (1/x)[Ei(x) - \log|x| - \gamma], \quad g(x) = e^x, \quad |x| \leq b \quad (5.29)$$

These functions, with the change of variable  $x = bt$ , simultaneously satisfy the differential equations

$$bt^2 \phi'(t) + bt\phi(t) - \psi(t) = -1 \quad (5.30)$$

$$\psi'(t) - b\psi(t) = 0, \quad -1 \leq t \leq 1 \quad (5.31)$$

Conversely,<sup>2</sup> any solution of equations 30 and 31 is equal to the functions given by equations 29 for the change of variable  $x = bt$ . Therefore, boundary conditions need not be imposed for the solution of the differential equations.

A procedure similar to that of the previous section gives the coupled infinite recurrence relations

$$bA_1 + bA_3 - B_0 + B_2 = -2 \quad (5.32)$$

$$\left. \begin{aligned} kbA_{k-1} + 2(k+1)bA_{k+1} + (k+2)bA_{k+3} - 2B_k + 2B_{k+2} &= 0 \\ bB_{k-1} - 2kB_k - bB_{k+1} &= 0, \quad k = 1, 2, \dots \end{aligned} \right\} \quad (5.33)$$

where  $A_k$  and  $B_k$  are the Chebyshev coefficients of  $\phi(t)$  and  $\psi(t)$ , respectively.

Consider first the subsystem 33. If  $A_k = \alpha_k$  and  $B_k = \beta_k$  are a simultaneous solution of the system, which is homogeneous, then

$$\text{and} \quad \left. \begin{aligned} A_k &= c\alpha_k \\ B_k &= c\beta_k \end{aligned} \right\} \quad (5.34)$$

are also a solution for an arbitrary constant  $c$ . Thus based on considerations analogous to the solution of equations 21, 22, and 23, one can initiate an approximate solution of equations 32 and 33 by setting

$$\left. \begin{aligned} \alpha_M &= 0, \quad \alpha_k = 0 \quad \text{for } k \geq M+1 \\ \beta_M &= 1, \quad \beta_k = 0 \quad \text{for } k \geq M+1 \end{aligned} \right\} \quad (5.35)$$

and then determining  $\alpha_k$  and  $\beta_k$  ( $k = M-1, M-2, \dots, 0$ ) by backward recurrence by means of equation 33. The arbitrary constant  $c$  is determined by substituting 34 into 32.

### The Function $xe^{-x}Ei(x)$ on the Infinite Interval

Let

$$f(x) = xe^{-x}Ei(x), \quad -\infty < x \leq b < 0, \quad \text{or } 0 < b \leq x < \infty \quad (5.36)$$

By making the change of variables,

$$x = 2b/(t+1) \quad (5.37)$$

we can easily demonstrate that

$$f(x) = f[2b/(t+1)] = \phi(t) \quad (5.38)$$

---

<sup>2</sup>The general solution of the differential equations has the form

$$\begin{aligned} \phi(t) &= (c_1/t) + [Ei(bt) - \log|bt| - \gamma]/bt \\ \psi(t) &= c_2e^{bt} \end{aligned}$$

where the first and second terms of  $\phi(t)$  are, respectively, the complementary solution and a particular integral of equation 30. The requirement that  $\phi(t)$  is bounded makes the constant  $c_1 = 0$ . The fact that  $\psi(0) = 1$  is implicit in equation 30.

satisfies the differential equation

$$(t+1)^2 \phi'(t) + (t+1-2b)\phi(t) = -2b \quad (5.39)$$

with

$$\phi(1) = be^{-b} Ei(b) \quad (5.40)$$

An infinite system of equations involving the Chebyshev coefficients  $A_k$  of  $\phi(t)$  is deducible from equations 39 and 40 by the same procedure as applied to equations 13 and 14 to obtain the infinite system 20; it is given as follows.

$$\sum_{k=0}^{\infty} A_k = \phi(1) = be^{-b} Ei(b) \quad (5.41)$$

$$(1-2b)A_0 + 3A_1 + (3+2b)A_2 + A_3 = -4b \quad (5.42)$$

$$kA_{k-1} + 2[(2k+1)-2b]A_k + 6(k+1)A_{k+1} + 2(2k+3+2b)A_{k+2} + (k+2)A_{k+3} = 0, \quad k = 1, 2, \dots \quad (5.43)$$

As in the case of equations 21, 22 and 23, the solution of 41, 42 and 43 can be assumed to be

$$A_k = c_1 \alpha_k + c_2 \beta_k \quad (5.44)$$

with  $A_k$  vanishing for a  $k \geq M$ . Thus, we can set, say

$$\left. \begin{array}{ll} \alpha_{M-1} = 0 & , \quad \alpha_M = 1 \\ \beta_{M-1} = 1 & , \quad \beta_M = 0 \end{array} \right\} \quad (5.45)$$

and determine the trial solutions  $\alpha_k$  and  $\beta_k$  ( $k=M-1, M-2, \dots, 0$ ) by means of equation 43 by backward recurrence. The required solution of equations 41, 42, and 43 is then determined by substituting equation 44 in equations 41 and 42 and solving the resulting equations for  $c_1$  and  $c_2$ .

Loss of accuracy in the computation of  $A_k$  can also occur here, as in the solution of equations 21, 22 and 23, if the trial solutions are not sufficiently independent. The process used to improve the accuracy of  $A_k$  of the system 21, 22 and 23 can also be applied here.

For efficiency in computation, it is worth noting that for  $b < 0$  ( $-\infty < x \leq b < 0$ ) the boundary condition 40 is not required for the solution of equation 39 and 40. This follows from the fact that any solution<sup>3</sup> of the differential equation 39 is equal to  $xe^{-x} Ei(x)$  ( $x = 2b/(t+1)$ ). Hence the  $A_k$  of  $xe^{-x} Ei(x)$  for  $-\infty < x \leq b < 0$  can be obtained without the use of equation 39 and can be assumed to have the form

$$A_k = c\alpha_k, \quad (k = 0, 1, \dots, M) \quad (5.46)$$

The  $M+1$  values of  $\alpha_k$  can be generated by setting  $\alpha_M = 1$  and computing  $\alpha_k$  ( $k=0, 1, \dots, M-1$ ) by means of equation 43 by backward recurrence. The substitution of equation 46 into 42 then enables one to determine  $c$  from the resulting equation.

<sup>3</sup>The general solution of the differential equation 39. Since equation 39 has no bounded complementary solution for  $-\infty < x \leq b < 0$ , every solution of it is equal to the particular integral  $xe^{-x} Ei(x)$ . On the other hand, a solution of equation 39 for  $0 < x \leq b < \infty$  would, in general, involve the complementary function. Hence, boundary condition 40 is required to guarantee that the solution of equation 39 is equal to  $xe^{-x} Ei(x)$ .

### Remarks on Convergence and Accuracy

The Chebyshev coefficients of table 3 were computed on the IBM 7094 with 50-digit normalized floating-point arithmetic. In order to assure that the sequence of approximate solutions (see Discussion) converged to the limiting solution of the differential equation in question, a trial  $M$  was incremented by 4 until the approximate Chebyshev coefficients showed no change greater than or equal to  $0.5 \times 10^{-35}$ . Hence the maximum error is bounded by

$$0.5(M+1) \times 10^{-35} + \sum_{M+1}^{\infty} |A_k| \quad (5.47)$$

where the first term is the maximum error of the  $M+1$  approximate Chebyshev coefficients, and the sum is the maximum error of the truncated Chebyshev series of  $M+1$  terms. If the Chebyshev series is rapidly convergent, the maximum error of the approximate Chebyshev series should be of the order of  $10^{-30}$ . The coefficients of table 3 have been rounded to 30 digits, and higher terms for  $k > N$  giving the maximum residual

$$\sum_{k=N+1}^M |A_k| < 0.5 \times 10^{-30} \quad (5.48)$$

have been dropped. This should allow for evaluation of the relevant function that is accurate to 30 decimal places. Since the range of values of each function is bounded between  $2/5$  and  $5$ , the evaluated function should be good to 30 significant digits. Taylor series evaluation also checks with that of the function values of table 4 (computed with 30-digit floating-point arithmetic using the coefficients of table 3) for at least  $28\frac{1}{2}$  significant digits. Evaluation of  $Ei(x)$  using the coefficients of table 3 also checked with Murnaghan and Wrench [?] for  $28\frac{1}{2}$  significant figures.

**Table 3: Chebyshev Coefficients (a)**

$$xe^{-x} Ei(x) = \sum_{k=0}^{40} {}'A_k T_k(t), \quad t = (-20/x) - 1, \quad (-\infty < x \leq -10)$$

### 5.9.5 The Fresnel Integral[?, ?]

The Fresnel function is

$$C(x) - iS(x) = \int_0^x i^{-t^2} dt = \int_0^x \exp(-i\pi t^2/2) dt$$

We compare Axiom's results to Pearcey's tables which show the fresnel results to 6 decimal places. Computation of these values requires floats as the range quickly exceeds DoubleFloat. In each decade of the range we increase the number of terms by a factor of 10. So we compute with 10 terms in the range 0.0-10.0, 100 terms in 10.0-20.0, etc.

#### fresnelC

The fresnelC is the real portion of the Fresnel integral,  $C(u)$ , is defined as:

$$C(\sqrt{2x/\pi}) = \frac{1}{2} \int_0^x J_{-\frac{1}{2}}(t) dt = \frac{1}{\sqrt{(2\pi)}} \int_0^x \frac{\cos(t)}{\sqrt{t}} dt$$

where  $J_{-\frac{1}{2}}(t)$  is the Bessel function of the first kind of order  $-\frac{1}{2}$ .

This is related to the better known definition of  $C(u)$ , namely:

$$C(u) = \int_0^u \cos \frac{\pi t^2}{2} dt$$

where  $x = \pi u^2/2$ , or  $u = (2x/\pi)^{1/2}$

fresnelC is an analytic function of  $z$  with  $z=0$  as a two-sheeted branch point. Along the positive real axis the real definition gives:

$$C(0) = 0$$

$$\lim_{x \rightarrow +\infty} C(x) = \frac{1}{2}$$

The asymptotic behavior of the function in the corner  $|\arg z| \leq \pi - \epsilon$ , ( $\epsilon > 0$ ), for  $|z| \gg 1$  is given by

$$C(z) \approx \frac{1}{2} + \frac{\sin z}{\sqrt{2\pi z}} \left( 1 - \frac{1 \cdot 3}{(2z)^2} + \frac{1 \cdot 3 \cdot 5 \cdot 7}{(2z)^4} - \dots \right) - \frac{\cos z}{\sqrt{2\pi z}} \left( \frac{1}{(2z)} - \frac{1 \cdot 3 \cdot 5}{(2z)^3} + \dots \right)$$

(Note: Pearcey has a sign error for the second term ([?],p7)

The first approximation is

$$C(z) \approx \frac{1}{2} + \frac{\sin z}{\sqrt{2\pi z}}$$

Axiom uses the power series at the zero point:

$$C(z) = \sqrt{\frac{2z}{\pi}} \sum_{k=0}^n (-1)^k \frac{z^{2k}}{(4k+1)(2k)!}$$

— package DFSFUN DoubleFloatSpecialFunctions —

```
fresnelC(z:F):F ==
  z < 0 => error "fresnelC not defined for negative argument"
  z = 0 => 0

  reduce(_+, [(-1)**k*z**(2*k)/(factorial(2*k)*(4*k+1))_
    for k in 0..n])$LF
```

—————

### fresnelS

The fresnelS is the complex portion of the Fresnel integral,  $S(u)$ , is defined as:

$$S(\sqrt{2x/\pi}) = \frac{1}{2} \int_0^x J_{\frac{1}{2}}(t) dt = \frac{1}{\sqrt{(2\pi)}} \int_0^x \frac{\sin(t)}{\sqrt{t}} dt$$

where  $J_{\frac{1}{2}}(t)$  is the Bessel function of the first kind of order  $\frac{1}{2}$ .

This is related to the better known definition of  $S(u)$ , namely:

$$S(u) = \int_0^u \sin \frac{\pi t^2}{2} dt$$

where  $x = \pi u^2/2$ , or  $u = (2x/\pi)^{1/2}$

fresnelS is an analytic function of  $z$  with  $z=0$  as a two-sheeted branch point. Along the positive real axis the real definition gives:

$$S(0) = 0$$

$$\lim_{x \rightarrow +\infty} S(x) = \frac{1}{2}$$

The asymptotic behavior of the function in the corner  $|\arg z| \leq \pi - \epsilon$ , ( $\epsilon > 0$ ), for  $|z| \gg 1$  is given by

$$S(z) \approx \frac{1}{2} - \frac{\cos z}{\sqrt{2\pi z}} \left( 1 - \frac{1 \cdot 3}{(2z)^2} + \frac{1 \cdot 3 \cdot 5 \cdot 7}{(2z)^4} - \dots \right) - \frac{\sin z}{\sqrt{2\pi z}} \left( \frac{1}{(2z)} - \frac{1 \cdot 3 \cdot 5}{(2z)^3} + \dots \right)$$

The first approximation is

$$S(z) \approx \frac{1}{2} - \frac{\cos z}{\sqrt{2\pi z}}$$

Axiom uses the power series at the zero point:

$$S(z) = \sqrt{\frac{2z}{\pi}} \sum_{k=0}^n (-1)^k \frac{z^{2k+1}}{(4k+3)(2k+1)!}$$

## 5.12 package DRAWHACK DrawNumericHack

### 5.12.1 DrawNumericHack (DRAWHACK)

#### Exports:

coerce

— package DRAWHACK DrawNumericHack —

```

)abbrev package DRAWHACK DrawNumericHack
++ Author: Manuel Bronstein
++ Date Created: 21 Feb 1990
++ Date Last Updated: 21 Feb 1990
++ Basic Operations: coerce
++ Related Constructors:
++ Also See:
++ AMS Classifications:
++ Keywords:
++ References:
++ Description:
++ Hack for the draw interface. DrawNumericHack provides
++ a "coercion" from something of the form \spad{x = a..b} where \spad{a}
++ and b are
++ formal expressions to a binding of the form \spad{x = c..d} where c and d
++ are the numerical values of \spad{a} and b. This "coercion" fails if
++ \spad{a} and b contains symbolic variables, but is meant for expressions

```

```

++ involving %pi.
++ Note that this package is meant for internal use only.

DrawNumericHack(R:Join(OrderedSet,IntegralDomain,ConvertibleTo Float)):
  with coerce: SegmentBinding Expression R -> SegmentBinding Float
    ++ coerce(x = a..b) returns \spad{x = c..d} where c and d are the
    ++ numerical values of \spad{a} and b.
  == add
  coerce s ==
    map(numeric$Numeric(R),s)$SegmentBindingFunctions2(Expression R, Float)

    ++ sparsityIF(m) calculates the sparsity of a jacobian matrix
  jacobian: (VEDF,LS) -> MEDF
    ++ jacobian(v,w) is a local function to make a jacobian matrix
  eval: (MEDF,LS,VEDF) -> MEDF
    ++ eval(mat,symbols,values) evaluates a multivariable matrix at given values
    ++ for each of a list of variables
  stiffnessAndStabilityFactor: MEDF -> RSS
    ++ stiffnessAndStabilityFactor(me) calculates the stability and
    ++ stiffness factor of a system of first-order differential equations
    ++ (by evaluating the maximum difference in the real parts of the
    ++ negative eigenvalues of the jacobian of the system for which 0(10)
    ++ equates to mildly stiff wheras stiffness ratios of 0(10^6) are not
    ++ uncommon) and whether the system is likely to show any oscillations
    ++ (identified by the closeness to the imaginary axis of the complex
    ++ eigenvalues of the jacobian).
  stiffnessAndStabilityOfODEIF:ODEA -> RSS
    ++ stiffnessAndStabilityOfODEIF(ode) calculates the intensity values
    ++ of stiffness of a system of first-order differential equations
    ++ (by evaluating the maximum difference in the real parts of the
    ++ negative eigenvalues of the jacobian of the system for which 0(10)
    ++ equates to mildly stiff wheras stiffness ratios of 0(10^6) are not
    ++ uncommon) and whether the system is likely to show any oscillations
    ++ (identified by the closeness to the imaginary axis of the complex
    ++ eigenvalues of the jacobian).
    ++
    ++ It returns two values in the range [0,1].
  systemSizeIF:ODEA -> F
    ++ systemSizeIF(ode) returns the intensity value of the size of
    ++ the system of ODEs. 20 equations corresponds to the neutral
    ++ value. It returns a value in the range [0,1].
  expenseOfEvaluationIF:ODEA -> F
    ++ expenseOfEvaluationIF(o) returns the intensity value of the

```

```

++ cost of evaluating the input ODE. This is in terms of the number
++ of 'operational units'. It returns a value in the range
++ [0,1].\indent{20}
++ 400 'operation units' -> 0.75
++ 200 'operation units' -> 0.5
++ 83 'operation units' -> 0.25 \indent{15}
++ exponentiation = 4 units , function calls = 10 units.
accuracyIF:ODEA -> F
++ accuracyIF(o) returns the intensity value of the accuracy
++ requirements of the input ODE. A request of accuracy of 10^-6
++ corresponds to the neutral intensity. It returns a value
++ in the range [0,1].
intermediateResultsIF:ODEA -> F
++ intermediateResultsIF(o) returns a value corresponding to the
++ required number of intermediate results required and, therefore,
++ an indication of how much this would affect the step-length of the
++ calculation. It returns a value in the range [0,1].

# Chapter E

### 6.1 package EP EigenPackage

#### 6.1.1 EigenPackage (EP)

#### Exports:

characteristicPolynomial eigenvalues eigenvector eigenvectors generalizedEigenvector generalizedEigenvectors

— package EP EigenPackage —

```
)abbrev package EP EigenPackage
++ Author: P. Gianni
++ Date Created: summer 1986
++ Date Last Updated: October 1992
++ Basic Functions:
++ Related Constructors: NumericRealEigenPackage, NumericComplexEigenPackage,
++ RadicalEigenPackage
++ Also See:
++ AMS Classifications:
```

```

++ Keywords:
++ References:
++ Description:
++ This is a package for the exact computation of eigenvalues and eigenvectors.
++ This package can be made to work for matrices with coefficients which are
++ rational functions over a ring where we can factor polynomials.
++ Rational eigenvalues are always explicitly computed while the
++ non-rational ones are expressed in terms of their minimal
++ polynomial.
-- Functions for the numeric computation of eigenvalues and eigenvectors
-- are in numeigen spad.

```

```

EigenPackage(R) : C == T
where
  R      : GcdDomain
  P      ==> Polynomial R
  F      ==> Fraction P
  SE     ==> Symbol()
  SUP    ==> SparseUnivariatePolynomial(P)
  SUF    ==> SparseUnivariatePolynomial(F)
  M      ==> Matrix(F)
  NNI    ==> NonNegativeInteger
  ST     ==> SuchThat(SE,P)

Eigenvalue ==> Union(F,ST)
EigenForm  ==> Record(eigval:Eigenvalue,eigmult:NNI,eigvec : List M)
GenEigen   ==> Record(eigval:Eigenvalue,geneigvec:List M)

C == with
characteristicPolynomial : (M,Symbol) -> P
  ++ characteristicPolynomial(m,var) returns the
  ++ characteristicPolynomial of the matrix m using
  ++ the symbol var as the main variable.

characteristicPolynomial :      M      -> P
  ++ characteristicPolynomial(m) returns the
  ++ characteristicPolynomial of the matrix m using
  ++ a new generated symbol symbol as the main variable.

eigenvalues      :      M      -> List Eigenvalue
  ++ eigenvalues(m) returns the
  ++ eigenvalues of the matrix m which are expressible
  ++ as rational functions over the rational numbers.

eigenvector      :      (Eigenvalue,M) -> List M
  ++ eigenvector(eigval,m) returns the
  ++ eigenvectors belonging to the eigenvalue eigval
  ++ for the matrix m.

generalizedEigenvector : (Eigenvalue,M,NNI,NNI) -> List M

```

```

++ generalizedEigenvector(alpha,m,k,g)
++ returns the generalized eigenvectors
++ of the matrix relative to the eigenvalue alpha.
++ The integers k and g are respectively the algebraic and the
++ geometric multiplicity of the eigenvalue alpha.
++ alpha can be either rational or not.
++ In the second case alpha is the minimal polynomial of the
++ eigenvalue.

generalizedEigenvector : (EigenForm,M) -> List M
++ generalizedEigenvector(eigen,m)
++ returns the generalized eigenvectors
++ of the matrix relative to the eigenvalue eigen, as
++ returned by the function eigenvectors.

generalizedEigenvectors : M -> List GenEigen
++ generalizedEigenvectors(m)
++ returns the generalized eigenvectors
++ of the matrix m.

eigenvectors : M -> List(EigenForm)
++ eigenvectors(m) returns the eigenvalues and eigenvectors
++ for the matrix m.
++ The rational eigenvalues and the correspondent eigenvectors
++ are explicitly computed, while the non rational ones
++ are given via their minimal polynomial and the corresponding
++ eigenvectors are expressed in terms of a "generic" root of
++ such a polynomial.

--R
--E 15                                     Type: Expression(Integer)

```

Mathematica, Maple, and Maxima give:

$$\frac{3}{(3 * x + 6 * y)^2 \sqrt{1 - \frac{1}{(3 * x + 6 * y)^2}}}$$

which proceeds directly from the formula for the derivative of asec:

$$\frac{d}{dx} \operatorname{arcsec}(x) = \frac{1}{x \sqrt{x^2 - 1}}$$

— ElementaryFunction.input —

```
--S 16 of 32

--R
--R                                          Type: Expression(Integer)
--E 17
```

Mathematica, Maple, and Maxima give

$$-\frac{3}{(3 * x + 6 * y)^2 \sqrt{1 - \frac{1}{(3 * x + 6 * y)^2}}}$$

which is just the negative of the above result and we can see that the same analysis applies to explain the results.

--E 30

```

---

Mathematica gives

$$-\frac{3}{(3x+6y)\sqrt{\frac{1-3x-6y}{13x+6y}}(1+3x+6y)}$$

Maxima gives

$$-\frac{3}{(6y+3x)^2\sqrt{\frac{1}{(6y+3x)^2}-1}}$$

Maple gives

$$-\frac{3}{(3x+6y)^2\sqrt{\frac{1}{3x+6y}-1}\sqrt{\frac{1}{3x+6y}+1}}$$

Axiom cannot simplify these differences to zero but Maxima does which shows they are all equivalent answers.

— **ElementaryFunction.input** —

```

--S 31 of 32

--R                                          Type: Expression(Integer)
--E 31

```

---

Mathematica, Maple, and Maxima all generate the answer

$$-\frac{3}{(3x+6y)^2\sqrt{1+\frac{1}{(3x+6y)^2}}}$$

Axiom cannot simplify these differences to zero but Maxima does which shows they are all equivalent answers.

P2 ==> SparseMultivariatePolynomial(P, K)
LQ ==> LinearOrdinaryDifferentialOperator1 RF
REC ==> Record(particular: F, basis: List F)
U ==> Union(REC, "failed")
ALGOP ==> "%alg"

Exports ==> with
  solve: (L, F, SY) -> U
    ++ solve(op, g, x) returns either a solution of the ordinary differential
    ++ equation \spad{op y = g} or "failed" if no non-trivial solution can be
    ++ found; When found, the solution is returned in the form
    ++ \spad{[h, [b1,...,bm]]} where \spad{h} is a particular solution and
    ++ and \spad{[b1,...,bm]} are linearly independent solutions of the
    ++ associated homogenous equation \spad{op y = 0}.
    ++ A full basis for the solutions of the homogenous equation
    ++ is not always returned, only the solutions which were found;
    ++ \spad{x} is the dependent variable.
  solve: (L, F, SY, F, List F) -> Union(F, "failed")
    ++ solve(op, g, x, a, [y0,...,ym]) returns either the solution
    ++ of the initial value problem \spad{op y = g, y(a) = y0, y'(a) = y1,...}
    ++ or "failed" if the solution cannot be found;
    ++ \spad{x} is the dependent variable.

## 6.7 package EFSTRUC ElementaryFunctionStructurePackage

### 6.7.1 ElementaryFunctionStructurePackage (EFSTRUC)

#### Exports:

normalize   realElementary   rootNormalize   rischNormalize   tanQ   validExponential

## — package EFSTRUC ElementaryFunctionStructurePackage —

```

)abbrev package EFSTRUC ElementaryFunctionStructurePackage
++ Author: Manuel Bronstein
++ Date Created: 1987
++ Date Last Updated: 16 August 1995
++ Keywords: elementary, function, structure.
++ Description:
++ ElementaryFunctionStructurePackage provides functions to test the
++ algebraic independence of various elementary functions, using the
++ Risch structure theorem (real and complex versions).
++ It also provides transformations on elementary functions
++ which are not considered simplifications.

ElementaryFunctionStructurePackage(R,F): Exports == Implementation where
  R : Join(IntegralDomain, OrderedSet, RetractableTo Integer,
           LinearlyExplicitRingOver Integer)
  F : Join(AlgebraicallyClosedField, TranscendentalFunctionCategory,
           FunctionSpace R)

B ==> Boolean

UP ==> SparseUnivariatePolynomial F
SMP ==> SparseMultivariatePolynomial(R, K)
REC ==> Record(func:F, kers: List K, vals:List F)
U ==> Union(vec:Vector Q, func:F, fail: Boolean)
POWER ==> "%power"::SY
NTHR ==> "nthRoot"::SY

Exports ==> with
  normalize: F -> F
    ++ normalize(f) rewrites \spad{f} using the least possible number of
    ++ real algebraically independent kernels.
  normalize: (F, SY) -> F
    ++ normalize(f, x) rewrites \spad{f} using the least possible number of
    ++ real algebraically independent kernels involving \spad{x}.
  rischNormalize: (F, SY) -> REC
    ++ rischNormalize(f, x) returns \spad{[g, [k1,...,kn], [h1,...,hn]]}
    ++ such that \spad{g = normalize(f, x)} and each \spad{ki} was
    ++ rewritten as \spad{hi} during the normalization.
  realElementary: F -> F
    ++ realElementary(f) rewrites \spad{f} in terms of the 4 fundamental real
    ++ transcendental elementary functions: \spad{log, exp, tan, atan}.
  realElementary: (F, SY) -> F
    ++ realElementary(f,x) rewrites the kernels of \spad{f} involving

```

```

++ \spad{x} in terms of the 4 fundamental real
++ transcendental elementary functions: \spad{log, exp, tan, atan}.
validExponential: (List K, F, SY) -> Union(F, "failed")
++ validExponential([k1,...,kn],f,x) returns \spad{g} if \spad{exp(f)=g}
++ and \spad{g} involves only \spad{k1...kn}, and "failed" otherwise.
rootNormalize: (F, K) -> F
++ rootNormalize(f, k) returns \spad{f} rewriting either \spad{k} which
++ must be an nth-root in terms of radicals already in \spad{f}, or some
++ radicals in \spad{f} in terms of \spad{k}.
tanQ: (Q, F) -> F
++ tanQ(q,a) is a local function with a conditional implementation.

— package EFULS ElementaryFunctionsUnivariateLaurentSeries —

```

)abbrev package EFULS ElementaryFunctionsUnivariateLaurentSeries
++ Author: Clifton J. Williamson
++ Date Created: 6 February 1990
++ Date Last Updated: 25 February 1990
++ Keywords: elementary function, Laurent series

```

```

++ Examples:
++ References:
++ Description:
++ This package provides elementary functions on any Laurent series
++ domain over a field which was constructed from a Taylor series
++ domain. These functions are implemented by calling the
++ corresponding functions on the Taylor series domain. We also
++ provide 'partial functions' which compute transcendental
++ functions of Laurent series when possible and return "failed"
++ when this is not possible.

— package EFUPXS ElementaryFunctionsUnivariatePuisseuxSeries

```

)abbrev package EFUPXS ElementaryFunctionsUnivariatePuisseuxSeries
++ Author: Clifton J. Williamson
++ Date Created: 20 February 1990
++ Date Last Updated: 20 February 1990
++ References:
++ Description:
++ This package provides elementary functions on any Laurent series
++ domain over a field which was constructed from a Taylor series
++ domain. These functions are implemented by calling the
++ corresponding functions on the Taylor series domain. We also
++ provide 'partial functions' which compute transcendental
++ functions of Laurent series when possible and return "failed"
++ when this is not possible.

```

```

if Coef has Field then
  "***": (UPXS,RN) -> UPXS
    ++ z ** r raises a Puisseux series z to a rational power r

--% Exponentials and Logarithms

exp: UPXS -> UPXS
  ++ exp(z) returns the exponential of a Puisseux series z.
log: UPXS -> UPXS
  ++ log(z) returns the logarithm of a Puisseux series z.

--% TrigonometricFunctionCategory

sin: UPXS -> UPXS
  ++ sin(z) returns the sine of a Puisseux series z.
cos: UPXS -> UPXS
  ++ cos(z) returns the cosine of a Puisseux series z.
tan: UPXS -> UPXS
  ++ tan(z) returns the tangent of a Puisseux series z.
cot: UPXS -> UPXS
  ++ cot(z) returns the cotangent of a Puisseux series z.
sec: UPXS -> UPXS
  ++ sec(z) returns the secant of a Puisseux series z.
csc: UPXS -> UPXS
  ++ csc(z) returns the cosecant of a Puisseux series z.

--% ArcTrigonometricFunctionCategory

asin: UPXS -> UPXS
  ++ asin(z) returns the arc-sine of a Puisseux series z.
acos: UPXS -> UPXS
  ++ acos(z) returns the arc-cosine of a Puisseux series z.
atan: UPXS -> UPXS
  ++ atan(z) returns the arc-tangent of a Puisseux series z.
acot: UPXS -> UPXS
  ++ acot(z) returns the arc-cotangent of a Puisseux series z.
asec: UPXS -> UPXS
  ++ asec(z) returns the arc-secant of a Puisseux series z.
acsc: UPXS -> UPXS
  ++ acsc(z) returns the arc-cosecant of a Puisseux series z.

```

```
--% HyperbolicFunctionCategory
```

```
sinh: UPXS -> UPXS
  ++ sinh(z) returns the hyperbolic sine of a Puiseux series z.
cosh: UPXS -> UPXS
  ++ cosh(z) returns the hyperbolic cosine of a Puiseux series z.
tanh: UPXS -> UPXS
  ++ tanh(z) returns the hyperbolic tangent of a Puiseux series z.
coth: UPXS -> UPXS
  ++ coth(z) returns the hyperbolic cotangent of a Puiseux series z.
sech: UPXS -> UPXS
  ++ sech(z) returns the hyperbolic secant of a Puiseux series z.
csch: UPXS -> UPXS
  ++ csch(z) returns the hyperbolic cosecant of a Puiseux series z.
```

```
--% ArcHyperbolicFunctionCategory
```

```
asinh: UPXS -> UPXS
  ++ asinh(z) returns the inverse hyperbolic sine of a Puiseux series z.
acosh: UPXS -> UPXS
  ++ acosh(z) returns the inverse hyperbolic cosine of a Puiseux series z.
atanh: UPXS -> UPXS
  ++ atanh(z) returns the inverse hyperbolic tangent of a Puiseux series z.
acoth: UPXS -> UPXS
  ++ acoth(z) returns the inverse hyperbolic cotangent
  ++ of a Puiseux series z.
asech: UPXS -> UPXS
  ++ asech(z) returns the inverse hyperbolic secant of a Puiseux series z.
acsch: UPXS -> UPXS
  ++ acsch(z) returns the inverse hyperbolic cosecant
  ++ of a Puiseux series z.

---

Bug #100 is an infinite loop that eventually kills Axiom from the input

```
integrate((z^a+1)^b,z)
```

Line 2 of this function used to read:

```
symbolIfCan(k := kmax(l := union(l, varselect(kernels g, x))))
```

The loop occurs when the call to union causes

```
  a log(z)
 %e
```

to get added to the list every time. This gives the argument to kmax

```
  a log(z)
arg1= [z,%e      ]
```

and the result being

```
  a log(z)
 %e
```

We keep coming back to process this term, which ends up putting the same term back on the list and we loop. Waldek's solution is to remove the union call.

The original patch fixed the infinite regression mentioned above but caused Axiom to return a closed form of the integral:

$$\text{integrate}(\text{asech}(x)/x, x)$$

which should not have a closed form. This is referenced in the FriCAS SVN revision 279.

Essentially this new patch uses only logarithms of rational functions when integrating rational functions. It is unclear whether this is the correct fix.

#### — package INTEF ElementaryIntegration —

```
lfextendedint(f, x, g) ==
  empty?(l := varselect(kernels f, x)) => [x::F * f, 0]
  symbolIfCan(k := kmax(l))
  case SE =>
    g1 :=
      empty?(l1 := varselect(kernels g,x)) => 0::F
```

```

      kmax(l1) = k => g
      0::F
      map((x1:RF):F +-> multivariate(x1, k),
          extendedint(univariate(f, k),
                      univariate(g1, k)))
      is?(k, "exp"::SE) => expextint(f, x, k, g)
      prim?(k, x)      => primextint(f, x, k, g)
      has?(operator k, ALGOP) => alglfextint(f, k, l, x, g)
      unkextint(f, x, g)

```

—————  
 This is part of the fix for bug 100. Line 2 of this function used to read:

```

      symbolIfCan(k := kmax(l := union(l, vark(lu, x))) case SE =>

```

See the above discussion for why this causes an infinite loop.

## 6.15 package ERROR ErrorFunctions

### 6.15.1 ErrorFunctions (ERROR)

#### Exports:

error

— package ERROR ErrorFunctions —

```
)abbrev package ERROR ErrorFunctions
++ Author: Robert S. Sutor
++ Date Created: 29 May 1990
++ Date Last Updated: 29 May 1990
++ Description:
++ ErrorFunctions implements error functions callable from the system
++ interpreter. Typically, these functions would be called in user
++ functions. The simple forms of the functions take one argument
++ which is either a string (an error message) or a list of strings
++ which all together make up a message. The list can contain
++ formatting codes (see below). The more sophisticated versions takes
++ two arguments where the first argument is the name of the function
++ from which the error was invoked and the second argument is either a
++ string or a list of strings, as above. When you use the one
++ argument version in an interpreter function, the system will
++ automatically insert the name of the function as the new first
++ argument. Thus in the user interpreter function\br
++ \tab{5}\spad{f x == if x < 0 then error "negative argument" else x}\br
++ the call to error will actually be of the form\br
++ \tab{5}\spad{error("f","negative argument")}\br
```

```

++ because the interpreter will have created a new first argument.
++
++ Formatting codes:  error messages may contain the following
++ formatting codes (they should either start or end a string or
++ else have blanks around them):\br
++ \spad{%l}\tab{6}start a new line\br
++ \spad{%b}\tab{6}start printing in a bold font (where available)\br
++ \spad{%d}\tab{6}stop  printing in a bold font (where available)\br
++ \spad{%ceon}\tab{3}start centering message lines\br
++ \spad{%ceoff}\tab{2}stop  centering message lines\br
++ \spad{%rjon}\tab{3}start displaying lines "ragged left"\br
++ \spad{%rjoff}\tab{2}stop  displaying lines "ragged left"\br
++ \spad{%i}\tab{6}indent   following lines 3 additional spaces\br
++ \spad{%u}\tab{6}unindent following lines 3 additional spaces\br
++ \spad{%xN}\tab{5}insert N blanks (eg, \spad{%x10} inserts 10 blanks)
++
++ Examples:\br
++ 1.\spad{error "Whoops, you made a %l %ceon %b big %d %ceoff %l mistake!"}\br
++ 2.\spad{error ["Whoops, you made a", "%l %ceon %b", "big", \br
++ \tab{10}"%d %ceoff %l", "mistake!"]}

```

```

## — EuclideanGroebnerBasisPackage.help —

```
=====
euclideanGroebner examples
=====
```

Example to call euclideanGroebner:

```
a1:DMP([y,x],INT):= (9*x**2 + 5*x - 3)+ y*(3*x**2 + 2*x + 1)
a2:DMP([y,x],INT):= (6*x**3 - 2*x**2 - 3*x +3) + y*(2*x**3 - x - 1)
a3:DMP([y,x],INT):= (3*x**3 + 2*x**2) + y*(x**3 + x**2)
an:=[a1,a2,a3]
euclideanGroebner(an)
```

This will return the weak euclidean Groebner basis set.  
All reductions are total reductions.

You can get more information by providing a second argument.  
To get the reduced critical pairs do:

```
euclideanGroebner(an,"redcrit")
```

You can get other information by calling:

```
euclideanGroebner(an,"info")
```

which returns:

```
ci => Leading monomial for critpair calculation
tci => Number of terms of polynomial i
cj => Leading monomial for critpair calculation
tcj => Number of terms of polynomial j
c  => Leading monomial of critpair polynomial
tc => Number of terms of critpair polynomial
rc => Leading monomial of redcritpair polynomial
trc => Number of terms of redcritpair polynomial
tH => Number of polynomials in reduction list H
tD => Number of critpairs still to do
```

The three argument form returns all of the information:

```
euclideanGroebner(an,"info","redcrit")
```

The term ordering is determined by the polynomial type used.  
Suggested types include

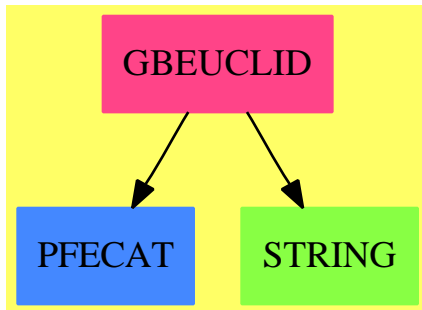

```
DistributedMultivariatePolynomial
HomogeneousDistributedMultivariatePolynomial
GeneralDistributedMultivariatePolynomial
```

### 6.16.1 EuclideanGroebnerBasisPackage (GBEUCLID)

**Exports:**

euclideanGroebner euclideanNormalForm

— package GBEUCLID EuclideanGroebnerBasisPackage —

```

)abbrev package GBEUCLID EuclideanGroebnerBasisPackage
++ Authors: Gebauer, Moeller
++ Date Created: 12-1-86
++ Date Last Updated: 2-28-91
++ Basic Functions:
++ Related Constructors: Ideal, IdealDecompositionPackage, GroebnerPackage
++ Also See:
++ AMS Classifications:
++ Keywords: groebner basis, polynomial ideal, euclidean domain
++ References:
++ Description:
++ \spadtype{EuclideanGroebnerBasisPackage} computes groebner
++ bases for polynomial ideals over euclidean domains.
++ The basic computation provides
++ a distinguished set of generators for these ideals.
++ This basis allows an easy test for membership: the operation

```

```

++ \spadfun{euclideanNormalForm} returns zero on ideal members. The string
++ "info" and "redcrit" can be given as additional args to provide
++ incremental information during the computation. If "info" is given,
++ a computational summary is given for each s-polynomial. If "redcrit"
++ is given, the reduced critical pairs are printed. The term ordering
++ is determined by the polynomial type used. Suggested types include
++ \spadtype{DistributedMultivariatePolynomial},
++ \spadtype{HomogeneousDistributedMultivariatePolynomial},
++ \spadtype{GeneralDistributedMultivariatePolynomial}.

### 6.17.1 EvaluateCycleIndicators (EVALCYC)

#### Exports:

eval

— package EVALCYC EvaluateCycleIndicators —

```

)abbrev package EVALCYC EvaluateCycleIndicators
++ Author: William H. Burge
++ Date Created: 1986
++ Date Last Updated: Feb 1992
++ Basic Operations:
++ Related Domains:
++ Also See:
++ AMS Classifications:
++ Keywords:
++ Examples:
++ References:
++ Description:
++ This package is to be used in conjunction with the CycleIndicators package.
++ It provides an evaluation function for SymmetricPolynomials.

```

```

EvaluateCycleIndicators(F):T==C where
  F:Algebra Fraction Integer
  I==>Integer
  L==>List
  SPOL==SymmetricPolynomial
  RN==>Fraction Integer
  PR==>Polynomial(RN)
  PTN==>Partition()
  lc ==> leadingCoefficient
  red ==> reductum
  T== with
    eval:((I->F),SPOL RN)->F

```

```

++\spad{eval(f,s)} evaluates the cycle index s by applying
++ the function f to each integer in a monomial partition,
++ forms their product and sums the results over all monomials.
C== add
  evp:((I->F),PTN)->F

## 6.24 package EXPRSOL ExpressionSolve

### 6.24.1 Bugs

```

seriesSolve(sin f x / cos x, f, x, [1])$EXPRSOL(INT, EXPR INT, UFPS EXPR INT, UFPS SUPEXPR EXPR INT)

```

returns

```
((0 . 1) 0 . 1) NonNullStream #<compiled-function |STREAM;generate;M$;62!0|> . UNPRINTABLE)
```

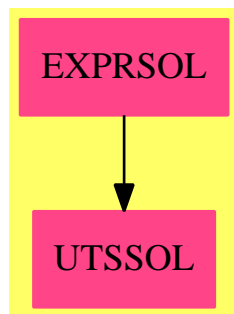

but

```
U ==> UFPS SUPEXPR EXPR INT
seriesSolve(s +-> sin s *((cos monomial(1,1)$U)**-1)$U, f, x, [0])$EXPRSOL(INT, EXPR INT, UFPS E
```

works. This is probably due to missing “/” in UFPS.

I’d really like to be able to specify a function that works for all domains in a category. For example,  $x \mapsto y(x)^2 + \sin x + x$  should work for EXPR INT as well as for UTS INT, both being domains having TranscendentalFunctionCategory.

### 6.24.2 ExpressionSolve (EXPRSOL)

```

---

The general method is to transform the given expression into a form which can then be compiled. There is currently no other way in Axiom to transform an expression into a function.

We need to replace the differentiation operator by the corresponding function in the power series category, and make composition explicit. Furthermore, we need to replace the variable by the corresponding variable in the power series. It turns out that the compiler doesn't find the right definition of `monomial(1,1)`. Thus we introduce it as a second argument. In fact, maybe that's even cleaner. Also, we need to tell the compiler that kernels that are independent of the main variable should be coerced to elements of the coefficient ring, since it will complain otherwise.

I cannot find an example for this behaviour right now. However, if I do use the `coerce`, the following fails:

```
seriesSolve(h x -1-x*h x *h(q*x), h, x, [1])
```

#### — package EXPRSOL ExpressionSolve —

LOCDF ==> List OrderedCompletion DoubleFloat
LEDF ==> List Expression DoubleFloat
PDF ==> Polynomial DoubleFloat
LDF ==> List DoubleFloat
INT ==> Integer
NNI ==> NonNegativeInteger
LS ==> List Symbol
EF2 ==> ExpressionFunctions2
NOA ==> Record(fn:EDF, init:LDF, lb:LOCDF, cf:LEDF, ub:LOCDF)
LSA ==> Record(lfn:LEDF, init:LDF)

E ==> with
  finiteBound:(LOCDF,DF) -> LDF
    ++ finiteBound(l,b) repaces all instances of an infinite entry in
    ++ \axiom{l} by a finite entry \axiom{b} or \axiom{-b}.
  sortConstraints:NOA -> NOA
    ++ sortConstraints(args) uses a simple bubblesort on the list of
    ++ constraints using the degree of the expression on which to sort.
    ++ Of course, it must match the bounds to the constraints.
  sumOfSquares:EDF -> Union(EDF,"failed")
    ++ sumOfSquares(f) returns either an expression for which the square is
    ++ the original function of "failed".
  splitLinear:EDF -> EDF
    ++ splitLinear(f) splits the linear part from an expression which it
    ++ returns.
  simpleBounds?:LEDF -> Boolean
    ++ simpleBounds?(l) returns true if the list of expressions l are
    ++ simple.
  linear?:LEDF -> Boolean
    ++ linear?(l) returns true if all the bounds l are either linear or
    ++ simple.
  linear?:EDF -> Boolean
    ++ linear?(e) tests if \axiom{e} is a linear function.
  linearMatrix:(LEDF, NNI) -> MDF
    ++ linearMatrix(l,n) returns a matrix of coefficients of the linear
    ++ functions in \axiom{l}. If l is empty, the matrix has at least one
    ++ row.
  linearPart:LEDF -> LEDF
    ++ linearPart(l) returns the list of linear functions of \axiom{l}.
  nonLinearPart:LEDF -> LEDF
    ++ nonLinearPart(l) returns the list of non-linear functions of l.
  quadratic?:EDF -> Boolean
    ++ quadratic?(e) tests if \axiom{e} is a quadratic function.

```

```

variables:LSA -> LS
  ++ variables(args) returns the list of variables in \axiom{args.lfn}
varList:(EDF,NNI) -> LS
  ++ varList(e,n) returns a list of \axiom{n} indexed variables with name
  ++ as in \axiom{e}.
changeNameToObjf:(Symbol,Result) -> Result
  ++ changeNameToObjf(s,r) changes the name of item \axiom{s} in \axiom{r}
  ++ to objf.
expenseOfEvaluation:LSA -> F
  ++ expenseOfEvaluation(o) returns the intensity value of the
  ++ cost of evaluating the input set of functions. This is in terms
  ++ of the number of ‘operational units’. It returns a value
  ++ in the range [0,1].
optAttributes:Union(noa:NOA,lsa:LSA) -> List String
  ++ optAttributes(o) is a function for supplying a list of attributes
  ++ of an optimization problem.

— FactoredFunctions2.help —

=====

FactoredFunctions2 examples

=====

The FactoredFunctions2 package implements one operation, map, for applying an operation to every base in a factored object and to the unit.

```

double(x) == x + x
                                     Type: Void

f := factor(720)
   4 2
   2 3 5
                                     Type: Factored Integer

```

Actually, the map operation used in this example comes from Factored itself, since double takes an integer argument and returns an integer result.

```

map(double,f)
   4 2
   2 4 6 10
                                     Type: Factored Integer

```

If we want to use an operation that returns an object that has a type different from the operation's argument, the map in Factored cannot be used and we use the one in FactoredFunctions2.

```

makePoly(b) == x + b
               4      2
      (x + 1)(x + 2) (x + 3) (x + 5)

```

Type: Factored Polynomial Integer

In fact, the "2" in the name of the package means that we might be using factored objects of two different types.

```
g := map(makePoly,f)
```

It is important to note that both versions of map destroy any information known about the bases (the fact that they are prime, for instance).

The flags for each base are set to "nil" in the object returned by map.

```
nthFlag(g,1)
"nil"
```

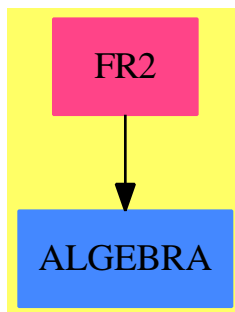

Type: Union("nil",...)

### 7.2.1 FactoredFunctions2 (FR2)

**Exports:**

map

— package FR2 FactoredFunctions2 —

```
)abbrev package FR2 FactoredFunctions2
++ Author: Robert S. Sutor
++ Date Created: 1987
++ Change History:
```

```

++ Basic Operations: map
++ Related Constructors: Factored
++ Also See:
++ AMS Classifications: 11A51, 11Y05
++ Keywords: map, factor
++ References:
++ Description:
++ \spadtype{FactoredFunctions2} contains functions that involve
++ factored objects whose underlying domains may not be the same.
++ For example, \spadfun{map} might be used to coerce an object of
++ type \spadtype{Factored(Integer)} to
++ \spadtype{Factored(Complex(Integer))}.

FactoredFunctions2(R, S): Exports == Implementation where
  R: IntegralDomain
  S: IntegralDomain

Exports ==> with
  map: (R -> S, Factored R) -> Factored S
    ++ map(fn,u) is used to apply the function \userfun{fn} to every
    ++ factor of \spadvar{u}. The new factored object will have all its
    ++ information flags set to "nil". This function is used, for
    ++ example, to coerce every factor base to another type.

Implementation ==> add
  map(func, f) ==
    func(unit f) *
      _*/[nilFactor(func(g.factor), g.exponent) for g in factors f]

## 7.3 package FRUTIL FactoredFunctionUtilities

### 7.3.1 FactoredFunctionUtilities (FRUTIL)

#### Exports:

mergeFactors   refine

— package FRUTIL FactoredFunctionUtilities —

```
)abbrev package FRUTIL FactoredFunctionUtilities
++ Author:
++ Date Created:
++ Change History:
++ Basic Operations: refine, mergeFactors
++ Related Constructors: Factored
++ Also See:
++ AMS Classifications: 11A51, 11Y05
++ Keywords: factor
++ References:
++ Description:
++ \spadtype{FactoredFunctionUtilities} implements some utility
++ functions for manipulating factored objects.

FactoredFunctionUtilities(R): Exports == Implementation where
  R: IntegralDomain
  FR ==> Factored R

Exports ==> with
  refine: (FR, R-> FR) -> FR
    ++ refine(u,fn) is used to apply the function \userfun{fn} to
    ++ each factor of \spadvar{u} and then build a new factored
    ++ object from the results. For example, if \spadvar{u} were
    ++ created by calling \spad{nilFactor(10,2)} then
    ++ \spad{refine(u,factor)} would create a factored object equal
    ++ to that created by \spad{factor(100)} or
    ++ \spad{primeFactor(2,2) * primeFactor(5,2)}.
```

```

mergeFactors: (FR,FR) -> FR
  ++ mergeFactors(u,v) is used when the factorizations of \spadvar{u}
  ++ and \spadvar{v} are known to be disjoint, e.g. resulting from a
  ++ content/primitive part split. Essentially, it creates a new
  ++ factored object by multiplying the units together and appending
  ++ the lists of factors.

Implementation ==> add
  fg: FR
  func: R -> FR
  fUnion ==> Union("nil", "sqfr", "irred", "prime")
  FF      ==> Record(flg: fUnion, fctr: R, xpnt: Integer)

mergeFactors(f,g) ==
  makeFR(unit(f)*unit(g),append(factorList f,factorList g))

refine(f, func) ==
  u := unit(f)
  l: List FF := empty()
  for item in factorList f repeat
    fitem := func item.fctr
    u := u*unit(fitem) ** (item.xpnt :: NonNegativeInteger)
    if item.xpnt = 1 then
      l := concat(factorList fitem,l)
    else l := concat([[v.flg,v.fctr,v.xpnt*item.xpnt]
                      for v in factorList fitem],l)
  makeFR(u,l)

++ Date Created: March 12, 1992
++ Date Last Updated:
++ Basic Functions:
++ Related Constructors:
++ Also See:
++ AMS Classifications:
++ Keywords:
++ References:
++ Description:
++ This package provides utilities used by the factorizers
++ which operate on polynomials represented as univariate polynomials
++ with multivariate coefficients.

FactoringUtilities(E,OV,R,P) : C == T where
  E : OrderedAbelianMonoidSup
  OV : OrderedSet
  R : Ring
  P : PolynomialCategory(R,E,OV)

  SUP ==> SparseUnivariatePolynomial
  NNI ==> NonNegativeInteger
  Z ==> Integer

C == with
  completeEval : (SUP P,List OV,List R) -> SUP R
  
```

```

++ completeEval(upoly, lvar, lval) evaluates the polynomial upoly
++ with each variable in lvar replaced by the corresponding value
++ in lval. Substitutions are done for all variables in upoly
++ producing a univariate polynomial over R.
degree      :      (SUP P,List OV)          -> List NNI
++ degree(upoly, lvar) returns a list containing the maximum
++ degree for each variable in lvar.
variables    :      SUP P                    -> List OV
++ variables(upoly) returns the list of variables for the coefficients
++ of upoly.
lowerPolynomial:      SUP P                  -> SUP R
++ lowerPolynomial(upoly) converts upoly to be a univariate polynomial
++ over R. An error if the coefficients contain variables.
raisePolynomial:      SUP R                  -> SUP P
++ raisePolynomial(rpoly) converts rpoly from a univariate polynomial
++ over r to be a univariate polynomial with polynomial coefficients.
normalDeriv   :      (SUP P,Z)              -> SUP P
++ normalDeriv(poly,i) computes the ith derivative of poly divided
++ by i!.
ran           :      Z                      -> R
++ ran(k) computes a random integer between -k and k as a member of R.

**Exports:**

factor	factorCantorZassenhaus	factorSquareFree
factorUsingMusser	factorUsingYun	irreducible?

— package FFFACTSE FiniteFieldFactorizationWithSizeParseBySide-  
Effect —

```

)abbrev package FFFACTSE FiniteFieldFactorizationWithSizeParseBySideEffect
++ Author: Patrice Naudin, Claude Quitte, Kaj Laursen
++ Date Created: September 1996
++ Date Last Updated: April 2010 by Tim Daly
++ Description:
++ Part of the package for Algebraic Function Fields in one variable (PAFF)
++ It has been modified (very slitley) so that each time the "factor"
++ function is used, the variable related to the size of the field
++ over which the polynomial is factorized is reset. This is done in
++ order to be used with a "dynamic extension field" which size is not
++ fixed but set before calling the "factor" function and which is
++ parse by side effect to this package via the function "size". See
++ the local function "initialize" of this package.
FiniteFieldFactorizationWithSizeParseBySideEffect(K : FiniteFieldCategory,

OUT  ==> OutputForm
SAE  ==> SimpleAlgebraicExtension
ARR  ==> PrimitiveArray(SI)
TERM ==> Record(value:GF,index:SI)
MM   ==> ModMonic(GF,SUP)
PF   ==> PrimeField

Exports ==> with

createZechTable: SUP -> ARR
++ createZechTable(f) generates a Zech logarithm table for the cyclic
++ group representation of a extension of the ground field by the
++ primitive polynomial f(x), i.e. \spad{Z(i)},
++ defined by  $x^{Z(i)} = 1+x^i$  is stored at index i.
++ This is needed in particular
++ to perform addition of field elements in finite fields represented
++ in this way. See \spadtype{FFCGP}, \spadtype{FFCGX}.
createMultiplicationTable: SUP -> V L TERM
++ createMultiplicationTable(f) generates a multiplication
++ table for the normal basis of the field extension determined
++ by f. This is needed to perform multiplications
++ between elements represented as coordinate vectors to this basis.
++ See \spadtype{FFNBP}, \spadtype{FFNBX}.
createMultiplicationMatrix: V L TERM -> M GF
++ createMultiplicationMatrix(m) forms the multiplication table
++ m into a matrix over the ground field.
-- only useful for the user to visualise the multiplication table
-- in a nice form
sizeMultiplication: V L TERM -> NNI
++ sizeMultiplication(m) returns the number of entries
++ of the multiplication table m.
-- the time of the multiplication of field elements depends
-- on this size
createLowComplexityTable: PI -> Union(Vector List TERM,"failed")
++ createLowComplexityTable(n) tries to find
++ a low complexity normal basis of degree n over GF
++ and returns its multiplication matrix
++ Fails, if it does not find a low complexity basis
createLowComplexityNormalBasis: PI -> Union(SUP, V L TERM)
++ createLowComplexityNormalBasis(n) tries to find a
++ a low complexity normal basis of degree n over GF
++ and returns its multiplication matrix
++ If no low complexity basis is found it calls
++ \axiomFunFrom{createNormalPoly}{FiniteFieldPolynomialPackage}(n)
++ to produce a normal polynomial of degree n over GF

Implementation ==> add

++ Description:
++ FiniteFieldHomomorphisms(F1,GF,F2) exports coercion functions of
++ elements between the fields F1 and F2, which both must be
++ finite simple algebraic extensions of the finite ground field GF.

FiniteFieldHomomorphisms(F1,GF,F2): Exports == Implementation where
  F1: FiniteAlgebraicExtensionField(GF)
  GF: FiniteFieldCategory
  F2: FiniteAlgebraicExtensionField(GF)
-- the homorphism can only convert elements w.r.t. the last extension .
-- Adding a function 'groundField()' which returns the groundfield of GF
-- as a variable of type FiniteFieldCategory in the new compiler, one
-- could build up 'convert' recursively to get an homomorphism w.r.t
-- the whole extension.

++ Also See:
++ AMS Classifications:
++ Keywords:
++ References:
++ Description:
++ \spadtype{FortranCodePackage1} provides some utilities for
++ producing useful objects in FortranCode domain.
++ The Package may be used with the FortranCode domain and its
++ \spad{printCode} or possibly via an outputAsFortran.
++ (The package provides items of use in connection with ASPs
++ in the AXIOM-NAG link and, where appropriate, naming accords
++ with that in IRENA.)
++ The easy-to-use functions use Fortran loop variables I1, I2,
++ and it is users' responsibility to check that this is sensible.
++ The advanced functions use SegmentBinding to allow users control
++ over Fortran loop variable names.
-- Later might add functions to build
-- diagonalMatrix from List, i.e. the FC version of the corresponding
-- AXIOM function from MatrixCategory;
-- bandedMatrix, i.e. the full-matrix-FC version of the corresponding
-- AXIOM function in BandedMatrix Domain
  
```

```

— package FFFG FractionFreeFastGaussian —

```
)abbrev package FFFG FractionFreeFastGaussian
++ Author: Martin Rubey
++ Description:
++ This package implements the interpolation algorithm proposed in Beckermann,
++ Bernhard and Labahn, George, Fraction-free computation of matrix rational
++ interpolants and matrix GCDs, SIAM Journal on Matrix Analysis and
++ Applications 22.
++ The packages defined in this file provide fast fraction free rational
++ interpolation algorithms. (see FAMR2, FFFG, FFFGF, NEWTON)
```

```
FractionFreeFastGaussian(D, V): Exports == Implementation where
  D: Join(IntegralDomain, GcdDomain)
  V: AbelianMonoidRing(D, NonNegativeInteger) -- for example, SUP D
```

```
SUP ==> SparseUnivariatePolynomial
```

```
cFunction ==> (NonNegativeInteger, Vector SUP D) -> D
```

```
CoeffAction ==> (NonNegativeInteger, NonNegativeInteger, V) -> D
```

```
Exports == with
```

```
fffg: (List D, cFunction, List NonNegativeInteger) -> Matrix SUP D
++ \spad{fffg} is the general algorithm as proposed by Beckermann and
++ Labahn.
++
```

```

++ The first argument is the list of c_{i,i}. These are the only values
++ of C explicitly needed in \spad{fffg}.
++
++ The second argument c, computes c_k(M), i.e., c_k(.) is the dual basis
++ of the vector space V, but also knows about the special multiplication
++ rule as descibed in Equation (2). Note that the information about f
++ is therefore encoded in c.
++
++ The third argument is the vector of degree bounds n, as introduced in
++ Definition 2.1. In particular, the sum of the entries is the order of
++ the Mahler system computed.

interpolate: (List D, List D, NonNegativeInteger) -> Fraction SUP D
++ \spad{interpolate(xlist, ylist, deg} returns the rational function with
++ numerator degree at most \spad{deg} and denominator degree at most
++ \spad{#xlist-deg-1} that interpolates the given points using
++ fraction free arithmetic. Note that rational interpolation does not
++ guarantee that all given points are interpolated correctly:
++ unattainable points may make this impossible.

```

---

The following function could be moved to FFFGF, parallel to `generalInterpolation`. However, the reason for moving `generalInterpolation` for fractions to a separate package was the need of a generic signature, hence the extra argument `VF` to FFFGF. In the special case of rational interpolation, this extra argument is not necessary, since we are always returning a fraction of SUPs, and ignore `V`. In fact, `V` is not needed for `fffg` itself, only if we want to specify a `CoeffAction`.

Thus, maybe it would be better to move `fffg` to a separate package?

#### — package FFFG FractionFreeFastGaussian —

```

interpolate: (List Fraction D, List Fraction D, NonNegativeInteger)
-> Fraction SUP D
++ \spad{interpolate(xlist, ylist, deg} returns the rational function with
++ numerator degree \spad{deg} that interpolates the given points using
++ fraction free arithmetic.

generalInterpolation: (List D, CoeffAction,
    Vector V, List NonNegativeInteger) -> Matrix SUP D
++ \spad{generalInterpolation(C, CA, f, eta)} performs Hermite-Pade
++ approximation using the given action CA of polynomials on the elements
++ of f. The result is guaranteed to be correct up to order

```

```

++ |eta|-1. Given that eta is a "normal" point, the degrees on the
++ diagonal are given by eta. The degrees of column i are in this case
++ eta + e.i - [1,1,...,1], where the degree of zero is -1.
++
++ The first argument C is the list of coefficients c_{k,k} in the
++ expansion <x^k> z g(x) = sum_{i=0}^k c_{k,i} <x^i> g(x).
++
++ The second argument, CA(k, l, f), should return the coefficient of x^k
++ in z^l f(x).

generalInterpolation: (List D, CoeffAction,
                      Vector V, NonNegativeInteger, NonNegativeInteger)
                      -> Stream Matrix SUP D
++ \spad{generalInterpolation(C, CA, f, sumEta, maxEta)} applies
++ \spad{generalInterpolation(C, CA, f, eta)} for all possible \spad{eta}
++ with maximal entry \spad{maxEta} and sum of entries at most
++ \spad{sumEta}.
++
++ The first argument C is the list of coefficients c_{k,k} in the
++ expansion <x^k> z g(x) = sum_{i=0}^k c_{k,i} <x^i> g(x).
++
++ The second argument, CA(k, l, f), should return the coefficient of x^k
++ in z^l f(x).

generalCoefficient: (CoeffAction, Vector V,
                    NonNegativeInteger, Vector SUP D) -> D
++ \spad{generalCoefficient(action, f, k, p)} gives the coefficient of
++ x^k in p(z)\dot f(x), where the action of z^l on a polynomial in x is
++ given by action, i.e., action(k, l, f) should return the coefficient
++ of x^k in z^l f(x).

ShiftAction: (NonNegativeInteger, NonNegativeInteger, V) -> D
++ \spad{ShiftAction(k, l, g)} gives the coefficient of x^k in z^l g(x),
++ where \spad{z*(a+b*x+c*x^2+d*x^3+...)} = (b*x+2*c*x^2+3*d*x^3+...). In
++ terms of sequences, z*u(n)=n*u(n).

ShiftC: NonNegativeInteger -> List D
++ \spad{ShiftC} gives the coefficients c_{k,k} in the expansion <x^k> z
++ g(x) = sum_{i=0}^k c_{k,i} <x^i> g(x), where z acts on g(x) by
++ shifting. In fact, the result is [0,1,2,...]

DiffAction: (NonNegativeInteger, NonNegativeInteger, V) -> D
++ \spad{DiffAction(k, l, g)} gives the coefficient of x^k in z^l g(x),
++ where z*(a+b*x+c*x^2+d*x^3+...) = (a*x+b*x^2+c*x^3+...), i.e.,
++ multiplication with x.

DiffC: NonNegativeInteger -> List D
++ \spad{DiffC} gives the coefficients c_{k,k} in the expansion <x^k> z
++ g(x) = sum_{i=0}^k c_{k,i} <x^i> g(x), where z acts on g(x) by
++ shifting. In fact, the result is [0,0,0,...]

```

```

qShiftAction: (D, NonNegativeInteger, NonNegativeInteger, V) -> D
++ \spad{qShiftAction(q, k, l, g)} gives the coefficient of  $x^k$  in  $z^l$ 
++  $g(x)$ , where  $z*(a+b*x+c*x^2+d*x^3+...)=$ 
++  $(a+q*b*x+q^2*c*x^2+q^3*d*x^3+...)$ . In terms of sequences,
++  $z*u(n)=q^n*u(n)$ .

qShiftC: (D, NonNegativeInteger) -> List D
++ \spad{qShiftC} gives the coefficients  $c_{k,k}$  in the expansion  $\langle x^k \rangle z$ 
++  $g(x) = \sum_{i=0}^k c_{k,i} \langle x^i \rangle g(x)$ , where  $z$  acts on  $g(x)$  by
++ shifting. In fact, the result is  $[1, q, q^2, ...]$

v

```

---

The following function returns the stream of all possible degree vectors, beginning with  $v$ , where the degree vectors are sorted in reverse lexicographic order. Furthermore, the entries are all less or equal to  $p$  and their sum equals the sum of the entries of  $v$ . We assume that the entries of  $v$  are also all less or equal to  $p$ .

— package FFFG FractionFreeFastGaussian —

```

vectorStream(p: NonNegativeInteger, v: List NonNegativeInteger)
  : Stream List NonNegativeInteger == delay
next := nextVector!(p, copy v)
(next case "failed") => empty()$Stream(List NonNegativeInteger)
cons(next, vectorStream(p, next))

```

---

vectorStream2 skips every second entry of vectorStream.

— package FFFG FractionFreeFastGaussian —

```

vectorStream2(p: NonNegativeInteger, v: List NonNegativeInteger)

```

```

      : Stream List NonNegativeInteger == delay
next := nextVector!(p, copy v)
(next case "failed") => empty()$Stream(List NonNegativeInteger)
next2 := nextVector!(p, copy next)
(next2 case "failed") => cons(next, empty())
cons(next2, vectorStream2(p, next2))

```

---

This version of `generalInterpolation` returns a stream of solutions, one for each possible degree vector. Thus, it only needs to apply the previously defined `generalInterpolation` to each degree vector. These are generated by `vectorStream` and `vectorStream2` respectively.

If `f` consists of two elements only, we can skip every second degree vector: note that `fffg`, and thus also `generalInterpolation`, returns a matrix with `#f` columns, each corresponding to a solution of the interpolation problem. More precisely, the  $i^{\text{th}}$  column is a solution with degrees  $\eta - (1, 1, \dots, 1) + e_i$ . Thus, in the case of  $2 \times 2$  matrices, `vectorStream` would produce solutions corresponding to  $(d, 0), (d - 1, 1); (d - 1, 1), (d - 2, 2); (d - 2, 2), (d - 3, 3) \dots$ , i.e., every second matrix is redundant.

Although some redundancy exists also for higher dimensional `f`, the scheme becomes much more complicated, thus we did not implement it.

— package FFFG FractionFreeFastGaussian —

```

generalInterpolation(C: List D, coeffAction: CoeffAction,
                    f: Vector V,
                    sumEta: NonNegativeInteger,
                    maxEta: NonNegativeInteger)
: Stream Matrix SUP D ==

\getchunk{generate an initial degree vector}

if #f = 2 then
  map(x +-> generalInterpolation(C, coeffAction, f, x),
    cons(eta, vectorStream2(maxEta, eta)))
  $StreamFunctions2(List NonNegativeInteger,
    Matrix SUP D)
else
  map(x +-> generalInterpolation(C, coeffAction, f, x),
    cons(eta, vectorStream(maxEta, eta)))
  $StreamFunctions2(List NonNegativeInteger,
    Matrix SUP D)

```

---

We need to generate an initial degree vector, being the minimal element in reverse lexicographic order, i.e.,  $m, m, \dots, m, k, 0, 0, \dots$ , where  $m$  is `maxEta` and  $k$  is the remainder of `sumEta` divided by `maxEta`. This is done by the following code:

— generate an initial degree vector —

```
sum: Integer := sumEta
entry: Integer
eta: List NonNegativeInteger
:= [(if sum < maxEta _
    then (entry := sum; sum := 0) _
    else (entry := maxEta; sum := sum - maxEta); _
    entry::NonNegativeInteger) for i in 1..#f]
```

—————

We want to generate all vectors with sum of entries being at most sumEta. Therefore the following is incorrect.

— BUG generate an initial degree vector —

```
-- (sum > 0) => empty()$Stream(Matrix SUP D)
```

—————

— package FFFG FractionFreeFastGaussian —

```
-----
-- rational interpolation
-----
```

```
interpolate(x: List Fraction D, y: List Fraction D, d: NonNegativeInteger)
: Fraction SUP D ==
gx := splitDenominator(x)$InnerCommonDenominator(D, Fraction D, _
List D, _
List Fraction D)
gy := splitDenominator(y)$InnerCommonDenominator(D, Fraction D, _
List D, _
List Fraction D)
r := interpolate(gx.num, gy.num, d)
elt(numer r, monomial(gx.den,1))/(gy.den*elt(denom r, monomial(gx.den,1)))
```

```
interpolate(x: List D, y: List D, d: NonNegativeInteger): Fraction SUP D ==
-- berechne Interpolante mit Graden d und N-d-1
if (N := #x) ~= #y then
    error "interpolate: number of points and values must match"
if N <= d then
    error "interpolate: numerator degree must be smaller than number of data points"
c: cFunction := (s,u) +-> y.s * elt(u.2, x.s) - elt(u.1, x.s)
eta: List NonNegativeInteger := [d, (N-d)::NonNegativeInteger]
M := fffg(x, c, eta)
```

```

if zero?(M.(2,1)) then M.(1,2)/M.(2,2)
else M.(1,1)/M.(2,1)

```

Because of Lemma 5.3,  $M.1.(2,1)$  and  $M.1.(2,2)$  cannot both vanish, since **eta\_sigma** is always  $\sigma$ -normal by Theorem 7.2 and therefore also para-normal, see Definition 4.2.

Because of Lemma 5.1 we have that  $M.1.(*,2)$  is a solution of the interpolation problem, if  $M.1.(2,1)$  vanishes.

— package FFFG FractionFreeFastGaussian —

```

-----
-- fffg
-----

```

recurrence computes the new matrix  $M$ , according to the following formulas (cf. Table 2 in Beckermann and Labahn):

$$\begin{aligned}
& \text{Increase order} \\
& \text{for } \ell = 1 \dots m, \ell \neq \pi \\
& \mathbf{M}_{\sigma+1}^{(\cdot, \ell)} := \left( \mathbf{M}_{\sigma}^{(\cdot, \ell)} r^{(\pi)} - \mathbf{M}_{\sigma}^{(\cdot, \pi)} r^{(\ell)} \right) / d_{\sigma} \\
& \text{Increase order in column } \pi \\
& \mathbf{M}_{\sigma+1}^{(\cdot, \pi)} := (z - c_{\sigma, \sigma}) \mathbf{M}_{\sigma}^{(\cdot, \pi)} \\
& \text{Adjust degree constraints:} \\
& \mathbf{M}_{\sigma+1}^{(\cdot, \pi)} := \left( \mathbf{M}_{\sigma+1}^{(\cdot, \pi)} r^{(\pi)} - \sum_{\ell \neq \pi} \mathbf{M}_{\sigma+1}^{(\cdot, \ell)} p^{(\ell)} \right) / d_{\sigma}
\end{aligned}$$

Since we do not need the matrix  $\mathbf{M}_{\sigma}$  anymore, we drop the index and update the matrix destructively. In the following, we write  $\mathbf{Ck}$  for  $c_{\sigma, \sigma}$ .

— package FFFG FractionFreeFastGaussian —

```

### 7.31.2 differentiation of special functions

In the following we define the symbolic derivatives of the special functions we provide. The formulas we use for the Bessel functions can be found in Milton Abramowitz and Irene A. Stegun, eds. (1965). Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables. New York: Dover. ISBN 0-486-61272-4, Equations 9.1.27 and 9.6.26. Up to patch-50 the formula for  $K$  missed the minus sign. (Issue #355)

We do not attempt to provide formulas for the derivative with respect to the first argument currently. Instead, we leave such derivatives unevaluated.

— package FSPECF FunctionalSpecialFunction —

```

import Fraction Integer
ahalf: F := recip(2::F)::F
athird: F := recip(3::F)::F
twothirds: F := 2*recip(3::F)::F

```

---

We need to get hold of the differentiation operator as modified by FunctionSpace. Otherwise, for example, display will be ugly. We accomplish that by differentiating an operator, which will certainly result in a single kernel only.

— package FSPECF FunctionalSpecialFunction —

```

dummyArg: SE := new()$SE
opdiff := operator first kernels D((operator(new()$SE)$BasicOperator)
                                   (dummyArg::F), dummyArg)

```

---

The differentiation operator `opdiff` takes three arguments corresponding to

$$F_{,i}(a_1, a_2, \dots, a_n) :$$

1.  $F(a_1, \dots, dm, \dots, a_n)$ , where the  $i^{\text{th}}$  argument is a dummy variable,

2.  $dm$ , the dummy variable, and
3.  $a_i$ , the point at which the differential is evaluated.

In the following, it seems to be safe to use the same dummy variable throughout. At least, this is done also in `FunctionSpace`, and did not cause problems.

The operation `symbolicGrad` returns the first component of the gradient of `op l`.

— package FSPECF FunctionalSpecialFunction —

```
dm := new()$SE :: F

iBesselJ(l: List F, t: SE): F ==
  n := first l; x := second l
  differentiate(n, t)*kernel(opdiff, [opBesselJ [dm, x], dm, n])
  + differentiate(x, t) * ahalf * (besselJ (n-1,x) - besselJ (n+1,x))

iBesselY(l: List F, t: SE): F ==
  n := first l; x := second l
  differentiate(n, t)*kernel(opdiff, [opBesselY [dm, x], dm, n])
  + differentiate(x, t) * ahalf * (besselY (n-1,x) - besselY (n+1,x))

iBesselI(l: List F, t: SE): F ==
  n := first l; x := second l
  differentiate(n, t)*kernel(opdiff, [opBesselI [dm, x], dm, n])
  + differentiate(x, t)* ahalf * (besselI (n-1,x) + besselI (n+1,x))

iBesselK(l: List F, t: SE): F ==
  n := first l; x := second l
  differentiate(n, t)*kernel(opdiff, [opBesselK [dm, x], dm, n])
  - differentiate(x, t)* ahalf * (besselK (n-1,x) + besselK (n+1,x))
```

—————

For the moment we throw an error if we try to differentiate polygamma with respect to the first argument.

— package FSPECF FunctionalSpecialFunction —

```
ipolygamma(l: List F, x: SE): F ==
  member?(x, variables first l) =>
    error "cannot differentiate polygamma with respect to the first argument"
  n := first l; y := second l
  differentiate(y, x)*polygamma(n+1, y)
iBetaGrad1(l: List F): F ==
  x := first l; y := second l
  Beta(x,y)*(digamma x - digamma(x+y))
```

```

iBetaGrad2(l: List F): F ==
  x := first l; y := second l
  Beta(x,y)*(digamma y - digamma(x+y))

if F has ElementaryFunctionCategory then
  iGamma2(l: List F, t: SE): F ==
    a := first l; x := second l
    differentiate(a, t)*kernel(opdiff, [opGamma2 [dm, x], dm, a])
    - differentiate(x, t)* x ** (a - 1) * exp(-x)
  setProperty(opGamma2, SPECIALDIFF, iGamma2@((List F, SE)->F)
              pretend None)

```

---

Finally, we tell Axiom to use these functions for differentiation. Note that up to patch-50, the properties for the Bessel functions were set using `derivative(oppolygamma, [lzero, ipolygammaGrad])`, where `lzero` returned zero always. Trying to replace `lzero` by a function that returns the first component of the gradient failed, it resulted in an infinite loop for `integrate(D(besselJ(a,x),a),a)`.

— package FSPECF FunctionalSpecialFunction —

```

derivative(opabs,      (x:F):F +-> abs(x) * inv(x))
derivative(opGamma,   (x:F):F +-> digamma x * Gamma x)
derivative(opBeta,    [iBetaGrad1, iBetaGrad2])
derivative(opdigamma, (x:F):F +-> polygamma(1, x))
setProperty(oppolygamma, SPECIALDIFF, ipolygamma@((List F, SE)->F)
           pretend None)
setProperty(opBesselJ, SPECIALDIFF, iBesselJ@((List F, SE)->F)
           pretend None)
setProperty(opBesselY, SPECIALDIFF, iBesselY@((List F, SE)->F)
           pretend None)
setProperty(opBesselI, SPECIALDIFF, iBesselI@((List F, SE)->F)
           pretend None)
setProperty(opBesselK, SPECIALDIFF, iBesselK@((List F, SE)->F)
           pretend None)

## 7.33 package FFINTBAS FunctionFieldIntegralBasis

### 7.33.1 FunctionFieldIntegralBasis (FFINTBAS)

#### Exports:

integralBasis localIntegralBasis

— package FFINTBAS FunctionFieldIntegralBasis —

```
)abbrev package FFINTBAS FunctionFieldIntegralBasis
++ Author: Victor Miller
++ Date Created: 9 April 1990
++ Date Last Updated: 20 September 1994
++ Keywords:
++ Examples:
++ References:
++ Description:
++ Integral bases for function fields of dimension one
++ In this package R is a Euclidean domain and F is a framed algebra
++ over R. The package provides functions to compute the integral
++ closure of R in the quotient field of F. It is assumed that
++ \spad{char(R/P) = char(R)} for any prime P of R. A typical instance of
++ this is when \spad{R = K[x]} and F is a function field over R.
```

```

FunctionFieldIntegralBasis(R,UP,F): Exports == Implementation where
  R : EuclideanDomain with
      squareFree: $ -> Factored $
      ++ squareFree(x) returns a square-free factorisation of x
  UP : UnivariatePolynomialCategory R
  F : FramedAlgebra(R,UP)

  I ==> Integer
  Mat ==> Matrix R
  NNI ==> NonNegativeInteger

Exports ==> with
  integralBasis : () -> Record(basis: Mat, basisDen: R, basisInv:Mat)
      ++ \spad{integralBasis()} returns a record
      ++ \spad{[basis,basisDen,basisInv]} containing information regarding
      ++ the integral closure of R in the quotient field of F, where
      ++ F is a framed algebra with R-module basis \spad{w1,w2,...,wn}.
      ++ If \spad{basis} is the matrix \spad{(aij, i = 1..n, j = 1..n)}, then
      ++ the \spad{i}th element of the integral basis is
      ++ \spad{vi = (1/basisDen) * sum(aij * wj, j = 1..n)}, i.e. the
      ++ \spad{i}th row of \spad{basis} contains the coordinates of the
      ++ \spad{i}th basis vector. Similarly, the \spad{i}th row of the
      ++ matrix \spad{basisInv} contains the coordinates of \spad{wi} with
      ++ respect to the basis \spad{v1,...,vn}: if \spad{basisInv} is the
      ++ matrix \spad{(bij, i = 1..n, j = 1..n)}, then
      ++ \spad{wi = sum(bij * vj, j = 1..n)}.
  localIntegralBasis : R -> Record(basis: Mat, basisDen: R, basisInv:Mat)
      ++ \spad{integralBasis(p)} returns a record
      ++ \spad{[basis,basisDen,basisInv]} containing information regarding
      ++ the local integral closure of R at the prime \spad{p} in the quotient
      ++ field of F, where F is a framed algebra with R-module basis
      ++ \spad{w1,w2,...,wn}.
      ++ If \spad{basis} is the matrix \spad{(aij, i = 1..n, j = 1..n)}, then
      ++ the \spad{i}th element of the local integral basis is
      ++ \spad{vi = (1/basisDen) * sum(aij * wj, j = 1..n)}, i.e. the
      ++ \spad{i}th row of \spad{basis} contains the coordinates of the
      ++ \spad{i}th basis vector. Similarly, the \spad{i}th row of the

Exports ==> with

```

exprToXXP : (FE,B) -> XResult
  ++ exprToXXP(fcn,posCheck?) converts the expression \spad{fcn} to
  ++ an exponential expansion. If \spad{posCheck?} is true,
  ++ log's of negative numbers are not allowed nor are nth roots of
  ++ negative numbers with n even. If \spad{posCheck?} is false,
  ++ these are allowed.
localAbs: FE -> FE
  ++ localAbs(fcn) = \spad{abs(fcn)} or \spad{sqrt(fcn**2)} depending
  ++ on whether or not FE has a function \spad{abs}. This should be
  ++ a local function, but the compiler won't allow it.

++ AMS Classifications:
++ Keywords: elementary function, power series
++ Examples:
++ References:
++ Description:
++ This package converts expressions in some function space to power
++ series in a variable x with coefficients in that function space.
++ The function \spadfun{exprToUPS} converts expressions to power series
++ whose coefficients do not contain the variable x. The function
++ \spadfun{exprToGenUPS} converts functional expressions to power series
++ whose coefficients may involve functions of \spad{log(x)}.

  exprToUPS : (FE,B,S) -> Result
    ++ exprToUPS(fcn,posCheck?,atanFlag) converts the expression
    ++ \spad{fcn} to a power series. If \spad{posCheck?} is true,
    ++ log's of negative numbers are not allowed nor are nth roots of
    ++ negative numbers with n even. If \spad{posCheck?} is false,
    ++ these are allowed. \spad{atanFlag} determines how the case
    ++ \spad{atan(f(x))}, where \spad{f(x)} has a pole, will be treated.
    ++ The possible values of \spad{atanFlag} are \spad{"complex"},
    ++ \spad{"real: two sides"}, \spad{"real: left side"},
    ++ \spad{"real: right side"}, and \spad{"just do it"}.
    ++ If \spad{atanFlag} is \spad{"complex"}, then no series expansion
    ++ will be computed because, viewed as a function of a complex
    ++ variable, \spad{atan(f(x))} has an essential singularity.
    ++ Otherwise, the sign of the leading coefficient of the series
    ++ expansion of \spad{f(x)} determines the constant coefficient
    ++ in the series expansion of \spad{atan(f(x))}. If this sign cannot
    ++ be determined, a series expansion is computed only when
    ++ \spad{atanFlag} is \spad{"just do it"}. When the leading term
    ++ in the series expansion of \spad{f(x)} is of odd degree (or is a
    ++ rational degree with odd numerator), then the constant coefficient
    ++ in the series expansion of \spad{atan(f(x))} for values to the
    ++ left differs from that for values to the right. If \spad{atanFlag}
    ++ is \spad{"real: two sides"}, no series expansion will be computed.
    ++ If \spad{atanFlag} is \spad{"real: left side"} the constant
    ++ coefficient for values to the left will be used and if \spad{atanFlag}
    ++ \spad{"real: right side"} the constant coefficient for values to the
    ++ right will be used.
    ++ If there is a problem in converting the function to a power series,
    ++ a record containing the name of the function that caused the problem
    ++ and a brief description of the problem is returned.
    ++ When expanding the expression into a series it is assumed that
    ++ the series is centered at 0. For a series centered at a, the
    ++ user should perform the substitution \spad{x -> x + a} before calling
    ++ this function.

  exprToGenUPS : (FE,B,S) -> Result

```

```

++ exprToGenUPS(fcn,posCheck?,atanFlag) converts the expression
++ \spad{fcn} to a generalized power series. If \spad{posCheck?}
++ is true, log's of negative numbers are not allowed nor are nth roots
++ of negative numbers with n even. If \spad{posCheck?} is false,
++ these are allowed. \spad{atanFlag} determines how the case
++ \spad{atan(f(x))}, where \spad{f(x)} has a pole, will be treated.
++ The possible values of \spad{atanFlag} are \spad{"complex"},
++ \spad{"real: two sides"}, \spad{"real: left side"},
++ \spad{"real: right side"}, and \spad{"just do it"}.
++ If \spad{atanFlag} is \spad{"complex"}, then no series expansion
++ will be computed because, viewed as a function of a complex
++ variable, \spad{atan(f(x))} has an essential singularity.
++ Otherwise, the sign of the leading coefficient of the series
++ expansion of \spad{f(x)} determines the constant coefficient
++ in the series expansion of \spad{atan(f(x))}. If this sign cannot
++ be determined, a series expansion is computed only when
++ \spad{atanFlag} is \spad{"just do it"}. When the leading term
++ in the series expansion of \spad{f(x)} is of odd degree (or is a
++ rational degree with odd numerator), then the constant coefficient
++ in the series expansion of \spad{atan(f(x))} for values to the
++ left differs from that for values to the right. If \spad{atanFlag}
++ is \spad{"real: two sides"}, no series expansion will be computed.
++ If \spad{atanFlag} is \spad{"real: left side"} the constant
++ coefficient for values to the left will be used and if \spad{atanFlag}
++ \spad{"real: right side"} the constant coefficient for values to the
++ right will be used.
++ If there is a problem in converting the function to a power
++ series, we return a record containing the name of the function
++ that caused the problem and a brief description of the problem.
++ When expanding the expression into a series it is assumed that
++ the series is centered at 0. For a series centered at a, the
++ user should perform the substitution \spad{x -> x + a} before calling
++ this function.
localAbs: FE -> FE
++ localAbs(fcn) = \spad{abs(fcn)} or \spad{sqrt(fcn**2)} depending
++ on whether or not FE has a function \spad{abs}. This should be
++ a local function, but the compiler won't allow it.

++ Journal of the ACM, Vol. 25, No. 2, April 1978, pp. 271-282
++ Description:
++ \spadtype{GaloisGroupFactorizer} provides functions to factor resolvents.
-- improvements to do :
-- + reformulate the lifting problem in completeFactor -- See [1] (hard)
-- + implement algorithm RC -- See [1] (easy)
-- + use Dedekind's criterion to prove sometimes irreducibility (easy)
--   or even to improve early detection of true factors (hard)
-- + replace Sets by Bits

GaloisGroupFactorizer(UP): Exports == Implementation where

  LR ==> Record(left: UP, right: UP) -- Functional decomposition

Exports ==> with
  makeFR: FinalFact -> Factored UP
    ++ makeFR(flist) turns the final factorization of henselFact into a
    ++ \spadtype{Factored} object.
  degreePartition: DDList -> Multiset N
    ++ degreePartition(ddfactorization) returns the degree partition of
    ++ the polynomial f modulo p where ddfactorization is the distinct
    ++ degree factorization of f computed by ddFact for some prime p.
  musserTrials: () -> P
    ++ musserTrials() returns the number of primes that are tried in
    ++ \spadfun{modularFactor}.
  musserTrials: P -> P
    ++ musserTrials(n) sets to n the number of primes to be tried in
    ++ \spadfun{modularFactor} and returns the previous value.
  stopMusserTrials: () -> P
    ++ stopMusserTrials() returns the bound on the number of factors for
    ++ which \spadfun{modularFactor} stops to look for an other prime. You
    ++ will have to remember that the step of recombining the extraneous
    ++ factors may take up to \spad{2*stopMusserTrials()} trials.

```

```

stopMusserTrials: P -> P
  ++ stopMusserTrials(n) sets to n the bound on the number of factors for
  ++ which \spadfun{modularFactor} stops to look for an other prime. You
  ++ will have to remember that the step of recombining the extraneous
  ++ factors may take up to \spad{2*n} trials. Returns the previous
  ++ value.
numberOfFactors: DDList -> N
  ++ numberOfFactors(ddfactorization) returns the number of factors of
  ++ the polynomial f modulo p where ddfactorization is the distinct
  ++ degree factorization of f computed by ddFact for some prime p.
modularFactor: UP -> MFact
  ++ modularFactor(f) chooses a "good" prime and returns the factorization
  ++ of f modulo this prime in a form that may be used by
  ++ completeHensel. If prime is zero
  ++ it means that f has been proved to be irreducible over the integers
  ++ or that f is a unit (i.e. 1 or -1).
  ++ f shall be primitive (i.e. content(p)=1) and square free (i.e.
  ++ without repeated factors).
useSingleFactorBound?: () -> Boolean
  ++ useSingleFactorBound?() returns \spad{true} if algorithm with single
  ++ factor bound is used for factorization, \spad{false} for algorithm
  ++ with overall bound.
useSingleFactorBound: Boolean -> Boolean
  ++ useSingleFactorBound(b) chooses the algorithm to be used by the
  ++ factorizers: \spad{true} for algorithm with single
  ++ factor bound, \spad{false} for algorithm with overall bound.
  ++ Returns the previous value.
useEisensteinCriterion?: () -> Boolean
  ++ useEisensteinCriterion?() returns \spad{true} if factorizers
  ++ check Eisenstein's criterion before factoring.
useEisensteinCriterion: Boolean -> Boolean
  ++ useEisensteinCriterion(b) chooses whether factorizers check
  ++ Eisenstein's criterion before factoring: \spad{true} for
  ++ using it, \spad{false} else. Returns the previous value.
eisensteinIrreducible?: UP -> Boolean
  ++ eisensteinIrreducible?(p) returns \spad{true} if p can be
  ++ shown to be irreducible by Eisenstein's criterion,
  ++ \spad{false} is inconclusive.
tryFunctionalDecomposition?: () -> Boolean
  ++ tryFunctionalDecomposition?() returns \spad{true} if
  ++ factorizers try functional decomposition of polynomials before
  ++ factoring them.
tryFunctionalDecomposition: Boolean -> Boolean
  ++ tryFunctionalDecomposition(b) chooses whether factorizers have
  ++ to look for functional decomposition of polynomials
  ++ (\spad{true}) or not (\spad{false}). Returns the previous value.
factor: UP -> Factored UP
  ++ factor(p) returns the factorization of p over the integers.
factor: (UP,N) -> Factored UP
  ++ factor(p,r) factorizes the polynomial p using the single factor bound

```

```

++ algorithm and knowing that p has at least r factors.
factor: (UP,List N) -> Factored UP
++ factor(p,listOfDegrees) factorizes the polynomial p using the single
++ factor bound algorithm and knowing that p has for possible
++ splitting of its degree listOfDegrees.
factor: (UP,List N,N) -> Factored UP
++ factor(p,listOfDegrees,r) factorizes the polynomial p using the single
++ factor bound algorithm, knowing that p has for possible
++ splitting of its degree listOfDegrees and that p has at least r
++ factors.
factor: (UP,N,N) -> Factored UP
++ factor(p,d,r) factorizes the polynomial p using the single
++ factor bound algorithm, knowing that d divides the degree of all
++ factors of p and that p has at least r factors.
factorSquareFree: UP -> Factored UP
++ factorSquareFree(p) returns the factorization of p which is supposed
++ not having any repeated factor (this is not checked).
factorSquareFree: (UP,N) -> Factored UP
++ factorSquareFree(p,r) factorizes the polynomial p using the single
++ factor bound algorithm and knowing that p has at least r factors.
++ f is supposed not having any repeated factor (this is not checked).
factorSquareFree: (UP,List N) -> Factored UP
++ factorSquareFree(p,listOfDegrees) factorizes the polynomial p using
++ the single factor bound algorithm and knowing that p has for possible
++ splitting of its degree listOfDegrees.
++ f is supposed not having any repeated factor (this is not checked).
factorSquareFree: (UP,List N,N) -> Factored UP
++ factorSquareFree(p,listOfDegrees,r) factorizes the polynomial p using
++ the single factor bound algorithm, knowing that p has for possible
++ splitting of its degree listOfDegrees and that p has at least r
++ factors.
++ f is supposed not having any repeated factor (this is not checked).
factorSquareFree: (UP,N,N) -> Factored UP
++ factorSquareFree(p,d,r) factorizes the polynomial p using the single
++ factor bound algorithm, knowing that d divides the degree of all
++ factors of p and that p has at least r factors.
++ f is supposed not having any repeated factor (this is not checked).
factorOfDegree: (P,UP) -> Union(UP,"failed")
++ factorOfDegree(d,p) returns a factor of p of degree d.
factorOfDegree: (P,UP,N) -> Union(UP,"failed")
++ factorOfDegree(d,p,r) returns a factor of p of degree
++ d knowing that p has at least r factors.
factorOfDegree: (P,UP,List N) -> Union(UP,"failed")
++ factorOfDegree(d,p,listOfDegrees) returns a factor
++ of p of degree d knowing that p has for possible splitting of its
++ degree listOfDegrees.
factorOfDegree: (P,UP,List N,N) -> Union(UP,"failed")
++ factorOfDegree(d,p,listOfDegrees,r) returns a factor
++ of p of degree d knowing that p has for possible splitting of its
++ degree listOfDegrees, and that p has at least r factors.

```

```

factorOfDegree: (P,UP,List N,N,Boolean) -> Union(UP,"failed")
  ++ factorOfDegree(d,p,listOfDegrees,r,sqf) returns a
  ++ factor of p of degree d knowing that p has for possible splitting of
  ++ its degree listOfDegrees, and that p has at least r factors.
  ++ If \spad{sqf=true} the polynomial is assumed to be square free (i.e.
  ++ without repeated factors).
henselFact: (UP,Boolean) -> FinalFact
  ++ henselFact(p,sqf) returns the factorization of p, the result
  ++ is a Record such that \spad{contp=}content p,
  ++ \spad{factors=}List of irreducible factors of p with exponent.
  ++ If \spad{sqf=true} the polynomial is assumed to be square free (i.e.
  ++ without repeated factors).
btwFact: (UP,Boolean,Set N,N) -> FinalFact
  ++ btwFact(p,sqf,pd,r) returns the factorization of p, the result
  ++ is a Record such that \spad{contp=}content p,
  ++ \spad{factors=}List of irreducible factors of p with exponent.
  ++ If \spad{sqf=true} the polynomial is assumed to be square free (i.e.
  ++ without repeated factors).
  ++ pd is the \spadtype{Set} of possible degrees. r is a lower bound for
  ++ the number of factors of p. Please do not use this function in your
  ++ code because its design may change.

Exports ==>  with

    reset: () -> Void

    setCurve: PolyRing -> PolyRing

    homogenize: (PolyRing,Integer) -> PolyRing

    printInfo: List Boolean -> Void
        ++ printInfo(lbool) prints some information coming from various
        ++ package and domain used by this package.

    theCurve: () -> PolyRing
        ++ theCurve returns the specified polynomial for the package.

    genus: () -> NNI
        ++ genus returns the genus of the curve defined by the polynomial
        ++ given to the package.

    genusNeg: () -> INT

    desingTree: () -> List DesTree
        ++ desingTree returns the desingularisation trees at all singular
        ++ points of the curve defined by the polynomial given to the package.

    desingTreeWoFullParam : () -> List DesTree
        ++ desingTreeWoFullParam returns the desingularisation trees at all
        ++ singular points of the curve defined by the polynomial given to
        ++ the package. The local parametrizations are not computed.

    setSingularPoints: List ProjPt -> List ProjPt
        ++ setSingularPoints(lpt) sets the singular points to be used.
        ++ Beware: no attempt is made to check if the points are singular
        ++ or not, nor if all of the singular points are presents. Hence,
        ++ results of some computation maybe false. It is intend to be use
        ++ when one want to compute the singular points are computed by other
        ++ means than to use the function singularPoints.

    singularPoints: () -> List(ProjPt)
        ++ rationalPoints() returns the singular points of the
        ++ curve defined by the polynomial given to the package.
        ++ If the singular points lie in an extension of the specified ground
        ++ field an error message is issued specifying the extension degree
        ++ needed to find all singular points.

    parametrize: (PolyRing,Plc) -> PCS
        ++ parametrize(f,pl) returns a local parametrization of f at the place

```

```

++ pl.

lBasis: DIVISOR -> Record(num:List PolyRing, den: PolyRing)
  ++ lBasis computes a basis associated to the specified divisor

findOrderOfDivisor: (DIVISOR,Integer,Integer) -> _
  Record(ord:Integer,num:PolyRing,den:PolyRing,upTo:Integer)

interpolateForms: (DIVISOR,NNI) -> List(PolyRing)
  ++ interpolateForms(d,n) returns a basis of the interpolate forms of
  ++ degree n of the divisor d.

interpolateFormsForFact: (DIVISOR,List PolyRing) -> List(PolyRing)

eval: (PolyRing,Plc) -> K
  ++ eval(f,pl) evaluate f at the place pl.

eval: (PolyRing,PolyRing,Plc) -> K
  ++ eval(f,g,pl) evaluate the function f/g at the place pl.

eval: (FRACPOLY,Plc) -> K
  ++ eval(u,pl) evaluate the function u at the place pl.

evalIfCan: (PolyRing,Plc) -> Union(K,"failed")
  ++ evalIfCan(f,pl) evaluate f at the place pl
  ++ (returns "failed" if it is a pole).

evalIfCan: (PolyRing,PolyRing,Plc) -> Union(K,"failed")
  ++ evalIfCan(f,g,pl) evaluate the function f/g at the place pl
  ++ (returns "failed" if it is a pole).

evalIfCan: (FRACPOLY,Plc) -> Union(K,"failed")
  ++ evalIfCan(u,pl) evaluate the function u at the place pl
  ++ (returns "failed" if it is a pole).

intersectionDivisor: PolyRing -> DIVISOR
  ++ intersectionDivisor(pol) compute the intersection divisor
  ++ (the Cartier divisor) of the form pol with the curve. If some
  ++ intersection points lie in an extension of the ground field,
  ++ an error message is issued specifying the extension degree
  ++ needed to find all the intersection points.
  ++ (If pol is not homogeneous an error message is issued).

adjunctionDivisor: () -> DIVISOR
  ++ adjunctionDivisor computes the adjunction divisor of the plane
  ++ curve given by the polynomial crv.

placesAbove: ProjPt -> List Plc

pointDominateBy : Plc -> ProjPt

```

## 8.8. PACKAGE GPAFF GENERALPACKAGEFORALGEBRAICFUNCTIONFIELD 805

```

++ pointDominateBy(pl) returns the projective point dominated
++ by the place pl.

if K has Finite then --should we say LocallyAlgebraicallyClosedField??

rationalPlaces: () -> List Plc
  ++ rationalPlaces returns all the rational places of the
  ++ curve defined by the polynomial given to the package.

rationalPoints: () -> List(ProjPt)

LPolynomial: () -> SparseUnivariatePolynomial Integer
  ++ Returns the L-Polynomial of the curve.

LPolynomial: PI -> SparseUnivariatePolynomial Integer
  ++ LPolynomial(d) returns the L-Polynomial of the curve in
  ++ constant field extension of degree d.

classNumber: () -> Integer
  ++ Returns the class number of the curve.

placesOfDegree: PI -> List Plc
  ++ placesOfDegree(d) returns all places of degree d of the
  ++ curve.

numberOfPlacesOfDegree: PI -> Integer
  ++ returns the number of places of the given degree

numberRatPlacesExtDeg: PI -> Integer
  ++ numberRatPlacesExtDeg(n) returns the number of rational
  ++ places in the constant field extension of degree n

numberPlacesDegExtDeg: (PI, PI) -> Integer
  ++ numberRatPlacesExtDegExtDeg(d, n) returns the number of
  ++ places of degree d in the constant field extension of
  ++ degree n

ZetaFunction: () -> UTSZ
  ++ Returns the Zeta function of the curve. Calculated by
  ++ using the L-Polynomial

ZetaFunction: PI -> UTSZ
  ++ Returns the Zeta function of the curve in constant field
  ++ extension. Calculated by using the L-Polynomial

### 8.11.1 GenExEuclid (GENEEZ)

**Exports:**

compBound reduction solveid tablePow testModulus

## — package GENEZ GenExEuclid —

```

)abbrev package GENEZ GenExEuclid
++ Author : P.Gianni.
++ Date Created: January 1990
++ Description:
++ The equation \spad{Af+Bg=h} and its generalization to n polynomials
++ is solved for solutions over the R, euclidean domain.
++ A table containing the solutions of \spad{Af+Bg=x**k} is used.
++ The operations are performed modulus a prime
++ which are in principle big enough,
++ but the solutions are tested and, in case of failure, a hensel
++ lifting process is used to get to the right solutions.
++ It will be used in the factorization of multivariate polynomials
++ over finite field, with \spad{R=F[x]}.

GenExEuclid(R,BP) : C == T
where
  R      : EuclideanDomain
  PI     ==> PositiveInteger
  NNI    ==> NonNegativeInteger
  BP     : UnivariatePolynomialCategory R
  L      ==> List

C == with
  reduction: (BP,R) -> BP
    ++ reduction(p,prime) reduces the polynomial p modulo prime of R.
    ++ Note that this function is exported only because it's conditional.
  compBound: (BP,L BP) -> NNI
    ++ compBound(p,lp)
    ++ computes a bound for the coefficients of the solution
    ++ polynomials.
    ++ Given a polynomial right hand side p,
    ++ and a list lp of left hand side polynomials.
    ++ Exported because it depends on the valuation.
  tablePow : (NNI,R,L BP) -> Union(Vector(L BP),"failed")
    ++ tablePow(maxdeg,prime,lpol) constructs the table with the
    ++ coefficients of the Extended Euclidean Algorithm for lpol.
    ++ Here the right side is \spad{x**k}, for k less or equal to maxdeg.
    ++ The operation returns "failed" when the elements
    ++ are not coprime modulo prime.
  solveid : (BP,R,Vector L BP) -> Union(L BP,"failed")
    ++ solveid(h,table) computes the coefficients of the
    ++ extended euclidean algorithm for a list of polynomials
    ++ whose tablePow is table and with right side h.

```

```

testModulus : (R, L BP)    -> Boolean
  ++ testModulus(p,lp) returns true if the prime p
  ++ is valid for the list of polynomials lp, i.e. preserves
  ++ the degree and they remain relatively prime.

++ Description:
++ Rationalization of several types of genus 0 integrands;
++ This internal package rationalises integrands on curves of the form:\br
++ \tab{5}\spad{y^2 = a x^2 + b x + c}\br
++ \tab{5}\spad{y^2 = (a x + b) / (c x + d)}\br
++ \tab{5}\spad{f(x, y) = 0} where f has degree 1 in x\br
++ The rationalization is done for integration, limited integration,
```

```

++ extended integration and the risch differential equation;

### 8.14.1 GnuDraw (GDRAW)

**Exports:**

GospersMethod

— package GDRAW GnuDraw —

```

)abbrev package GDRAW GnuDraw
++ Author: Bill Page and David Cyganski
++ Date: June 25, 2008
++ Description:
++ This package provides support for gnuplot. These routines
++ generate output files contain gnuplot scripts that may be
++ processed directly by gnuplot. This is especially convenient
++ in the axiom-wiki environment where gnuplot is called from
++ LaTeX via gnuplottex.
GnuDraw(): Exports == Implementation where

=====
GroebnerFactorizationPackage examples
=====
```

Solving systems of polynomial equations with the Groebner basis algorithm can often be very time consuming because, in general, the algorithm has exponential run-time. These systems, which often come from concrete applications, frequently have symmetries which are not taken advantage of by the algorithm. However, it often happens in this case that the polynomials which occur during the Groebner calculations are reducible. Since Axiom has an excellent polynomial factorization algorithm, it is very natural to combine the Groebner and factorization algorithms.

GroebnerFactorizationPackage exports the groebnerFactorize operation which implements a modified Groebner basis algorithm. In this algorithm, each polynomial that is to be put into the partial list of the basis is first factored. The remaining calculation is split into as many parts as there are irreducible factors. Call these factors  $p_1, \dots, p_N$ . In the branches corresponding to  $p_2, \dots, p_N$ , the factor  $p_1$  can be divided out, and so on. This package also contains operations that allow you to specify the polynomials that are not zero on the common roots of the final Groebner basis.

Here is an example from chemistry. In a theoretical model of the cyclohexan  $C_6H_{12}$ , the six carbon atoms each sit in the center of gravity of a tetrahedron that has two hydrogen atoms and two carbon atoms at its corners. We first normalize and set the length of each edge to 1. Hence, the distances of one fixed carbon atom to each of its immediate neighbours is 1. We will denote the distances to the other three carbon atoms by  $x$ ,  $y$  and  $z$ .

A. Dress developed a theory to decide whether a set of points and distances between them can be realized in an  $n$ -dimensional space. Here, of course, we have  $n = 3$ .

```
mfzn : SQMATRIX(6,DMP([x,y,z],Fraction INT)) := _
[ [0,1,1,1,1,1], [1,0,1,8/3,x,8/3], [1,1,0,1,8/3,y], _
  [1,8/3,1,0,1,8/3], [1,x,8/3,1,0,1], [1,8/3,y,8/3,1,0] ]
+0 1 1 1 1 1+
|          |
|          8 8|
|1 0 1 - x -|
|          3 3|
|          |
|          8 |
|1 1 0 1 - y|
|          3 |
|          |
| 8          8|
```

$$\begin{array}{cccccc}
 | & 1 & - & 1 & 0 & 1 & - & | \\
 | & & 3 & & & & & 3 | \\
 | & & & & & & & | \\
 | & & & 8 & & & & | \\
 | & 1 & x & - & 1 & 0 & 1 & | \\
 | & & & 3 & & & & | \\

 | & & 8 & & 8 & & & | \\
 | & 1 & - & y & - & 1 & 0 & | \\
 + & & 3 & & 3 & & & +
 \end{array}$$

Type: SquareMatrix(6,DistributedMultivariatePolynomial([x,y,z],  
Fraction Integer))

For the cyclohexan, the distances have to satisfy this equation.

```

eq := determinant mfzn
      2 2    22 2    25 2    22 2    388    250    25 2    250    14575
- x y + -- x y - -- x + -- x y - --- x y - --- x - -- y - --- y + -----
      3      9      3      9      27      9      27      81
Type: DistributedMultivariatePolynomial([x,y,z],Fraction Integer)

```

They also must satisfy the equations given by cyclic shifts of the indeterminates.

```

Type: List List DistributedMultivariatePolynomial([x,y,z],Fraction Integer)

```

The union of the solutions of this list is the solution of our original problem. If we impose positivity conditions, we get two relevant ideals. One ideal is zero-dimensional, namely  $x = y = z = 11/3$ , and this determines the "boat" form of the cyclohexan. The other ideal is one-dimensional, which means that we have a solution space given by one parameter. This gives the "chair" form of the cyclohexan. The parameter describes the angle of the "back of the chair."

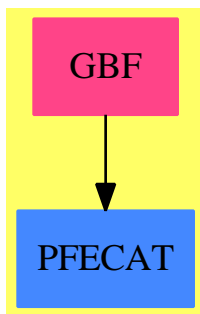

`groebnerFactorize` has an optional Boolean-valued second argument. When it is true partial results are displayed, since it may happen that the calculation does not terminate in a reasonable time. See the source code for `GroebnerFactorizationPackage` in `groebf.spad.pamphlet` for more details about the algorithms used.

++ Basic Operations: groebnerFactorize factorGroebnerBasis
++ Related Constructors:
++ Also See: GroebnerPackage, Ideal, IdealDecompositionPackage
++ AMS Classifications:
++ Keywords: groebner basis, groebner factorization, ideal decomposition
++ References:
++ Description:
++ \spadtype{GroebnerFactorizationPackage} provides the function
++ groebnerFactor" which uses the factorization routines of \Language{} to
++ factor each polynomial under consideration while doing the groebner basis
++ algorithm. Then it writes the ideal as an intersection of ideals
++ determined by the irreducible factors. Note that the whole ring may
++ occur as well as other redundancies. We also use the fact, that from the
++ second factor on we can assume that the preceding factors are
++ not equal to 0 and we divide all polynomials under considerations
++ by the elements of this list of "nonZeroRestrictions".
++ The result is a list of groebner bases, whose union of solutions
++ of the corresponding systems of equations is the solution of
++ the system of equation corresponding to the input list.
++ The term ordering is determined by the polynomial type used.
++ Suggested types include
++ \spadtype{DistributedMultivariatePolynomial},
++ \spadtype{HomogeneousDistributedMultivariatePolynomial},
++ \spadtype{GeneralDistributedMultivariatePolynomial}.

h : Dpol -- next polynomial from critical pairs
stopDividing : Boolean
-- STEP 1 do the next polynomials until a splitting is possible
-- In the first step we take the first polynomial of "inputPolys"
-- if empty, from list of critical pairs "lcP" and do the following:
-- Divide it, if possible, by the polynomials from "nonZeroRestrictions".
-- We factorize it and reduce each irreducible factor with respect to
-- "basis". If 0$Dpol occurs in the list we update the list and continue
-- with next polynomial.
-- If there are at least two (irreducible) factors
-- in the list of factors we finish STEP 1 and set a boolean variable
-- to continue with STEP 2, the splitting step.
-- If there is just one of it, we do the following:
-- If it is 1$Dpol we stop the whole calculation and put
-- [1$Dpol] into the listOfBases
-- Otherwise we update the "basis" and the other lists and continue
-- with next polynomial.

## — GroebnerPackage.help —

```
=====
groebner examples
=====
```

Example to call groebner:

```
s1:DMP[w,p,z,t,s,b]RN:= 45*p + 35*s - 165*b - 36
s2:DMP[w,p,z,t,s,b]RN:= 35*p + 40*z + 25*t - 27*s
s3:DMP[w,p,z,t,s,b]RN:= 15*w + 25*p*s + 30*z - 18*t - 165*b**2
s4:DMP[w,p,z,t,s,b]RN:= -9*w + 15*p*t + 20*z*s
s5:DMP[w,p,z,t,s,b]RN:= w*p + 2*z*t - 11*b**3
s6:DMP[w,p,z,t,s,b]RN:= 99*w - 11*b*s + 3*b**2
s7:DMP[w,p,z,t,s,b]RN:= b**2 + 33/50*b + 2673/10000
```

```
sn7:=[s1,s2,s3,s4,s5,s6,s7]
```

```
groebner(sn7,info)
```

groebner calculates a minimal Groebner Basis  
all reductions are TOTAL reductions

To get the reduced critical pairs do:

```
groebner(sn7,"redcrit")
```

You can get other information by calling:

```
groebner(sn7,"info")
```

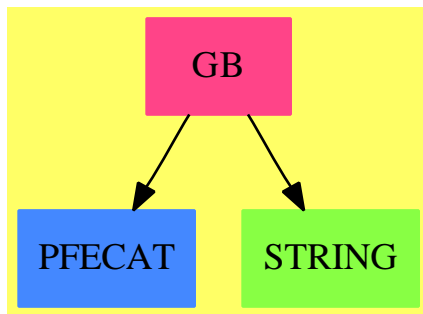

which returns:

```
ci => Leading monomial for critpair calculation
tci => Number of terms of polynomial i
cj => Leading monomial for critpair calculation
tcj => Number of terms of polynomial j
c  => Leading monomial of critpair polynomial
tc  => Number of terms of critpair polynomial
rc  => Leading monomial of redcritpair polynomial
trc => Number of terms of redcritpair polynomial
tF  => Number of polynomials in reduction list F
tD  => Number of critpairs still to do
```

### 8.20.1 GroebnerPackage (GB)

#### Exports:

groebner normalForm

— package GB GroebnerPackage —

```

)abbrev package GB GroebnerPackage
++ Authors: Gebauer, Trager
++ Date Created: 12-1-86
++ Date Last Updated: 2-28-91
++ Basic Functions: groebner normalForm
++ Related Constructors: Ideal, IdealDecompositionPackage
++ Also See:
++ AMS Classifications:
++ Keywords: groebner basis, polynomial ideal
++ References:
++ Description:
++ \spadtype{GroebnerPackage} computes groebner
++ bases for polynomial ideals. The basic computation provides a distinguished
++ set of generators for polynomial ideals over fields. This basis allows an
++ easy test for membership: the operation \spadfun{normalForm}
++ returns zero on ideal members. When the provided coefficient domain, Dom,
++ is not a field, the result is equivalent to considering the extended
++ ideal with \spadtype{Fraction(Dom)} as coefficients, but considerably more
++ efficient since all calculations are performed in Dom. Additional
++ argument "info" and "redcrit" can be given to provide incremental
++ information during computation. Argument "info" produces a computational
++ summary for each s-polynomial.
++ Argument "redcrit" prints out the reduced critical pairs. The term ordering

## 8.22 package GUESS Guess

The packages defined in this file enable Axiom to guess formulas for sequences of, for example, rational numbers or rational functions, given the first few terms. It extends and complements Christian Krattenthaler's program Rate and the relevant parts of Bruno Salvy and Paul Zimmermann's GFUN.

## 8.22.1 Guess (GUESS)

**Exports:**

diffHP	guess	guessADE	guessAlg	guessBinRat
guessExpRat	guessHP	guessHolo	guessPRec	guessPade
guessRat	guessRec	shiftHP		

The original code would not compile. This is a temporary replacement with changes marked with my initials. I will pick up the latest version sometime in the future and hope it compiles.  
(Tim Daly)

— package GUESS Guess —

```

)abbrev package GUESS Guess
++ Author: Martin Rubey, Timothy Daly
++ Description:

#### Exports:

increment incrementBy

— package INCRMAPS IncrementingMaps —

```

)abbrev package INCRMAPS IncrementingMaps
++ Author:
++ Date Created:
++ Date Last Updated: June 4, 1991
++ Basic Operations:
++ Related Domains: UniversalSegment
++ Also See:
++ AMS Classifications:
++ Keywords: equation
++ Examples:
++ References:
++ Description:
++ This package provides operations to create incrementing functions.

IncrementingMaps(R:Join(Monoid, AbelianSemiGroup)): with
  increment: () -> (R -> R)
    ++ increment() produces a function which adds \spad{1} to whatever
    ++ argument it is given. For example, if {f := increment()} then
    ++ \spad{f x} is \spad{x+1}.
  incrementBy: R -> (R -> R)
    ++ incrementBy(n) produces a function which adds \spad{n} to whatever
    ++ argument it is given. For example, if {f := increment(n)} then
    ++ \spad{f x} is \spad{x+n}.
== add
  increment() == x +-> 1 + x
  incrementBy n == x +-> n + x

### 10.14.1 InnerMultFact (INNMFACt)

#### Exports:

factor

— package INNMFACt InnerMultFact —

```
)abbrev package INNMFACt InnerMultFact
++ Author: P. Gianni
++ Date Created: 1983
++ Date Last Updated: Sept. 1990
++ Additional Comments: JHD Aug 1997
++ Basic Functions:
++ Related Constructors: MultivariateFactorize, AlgebraicMultFact
++ Also See:
++ AMS Classifications:
++ Keywords:
++ References:
++ Description:
++ This is an inner package for factoring multivariate polynomials
++ over various coefficient domains in characteristic 0.
++ The univariate factor operation is passed as a parameter.
++ Multivariate hensel lifting is used to lift the univariate
++ factorization

-- Both exposed functions call mFactor. This deals with issues such as
```

```
-- monomial factors, contents, square-freeness etc., then calls intfact.
-- This uses intChoose to find a "good" evaluation and factorise the
-- corresponding univariate, and then uses MultivariateLifting to find
-- the multivariate factors.
```

```

++ Description:
++ InnerNormalBasisFieldFunctions(GF) (unexposed):
++ This package has functions used by
++ every normal basis finite field extension domain.

InnerNormalBasisFieldFunctions(GF): Exports == Implementation where
  GF      : FiniteFieldCategory      -- the ground field

  PI      ==> PositiveInteger
  NNI     ==> NonNegativeInteger
  I       ==> Integer
  SI      ==> SingleInteger
  SUP     ==> SparseUnivariatePolynomial
  VGF     ==> Vector GF
  M       ==> Matrix
  V       ==> Vector
  L       ==> List
  OUT     ==> OutputForm
  TERM    ==> Record(value:GF,index:SI)
  MM      ==> ModMonic(GF,SUP GF)

Exports ==> with

  setFieldInfo: (V L TERM,GF) -> Void
```

```

++ setFieldInfo(m,p) initializes the field arithmetic, where m is
++ the multiplication table and p is the respective normal element
++ of the ground field GF.
random      : PI          -> VGF
++ random(n) creates a vector over the ground field with random entries.
index      : (PI,PI)     -> VGF
++ index(n,m) is a index function for vectors of length n over
++ the ground field.
pol        : VGF          -> SUP GF
++ pol(v) turns the vector \spad{[v0,...,vn]} into the polynomial
++ \spad{v0+v1*x+ ... + vn*x**n}.
xn         : NNI          -> SUP GF
++ xn(n) returns the polynomial \spad{x**n-1}.
dAndcExp   : (VGF,NNI,SI) -> VGF
++ dAndcExp(v,n,k) computes \spad{v**e} interpreting v as an element of
++ normal basis field. A divide and conquer algorithm similar to the
++ one from D.R.Stinson,
++ "Some observations on parallel Algorithms for fast exponentiation in
++ GF(2^n)", Siam J. Computation, Vol.19, No.4, pp.711-717, August 1990
++ is used. Argument k is a parameter of this algorithm.
repSq      : (VGF,NNI)    -> VGF
++ repSq(v,e) computes \spad{v**e} by repeated squaring,
++ interpreting v as an element of a normal basis field.
expPot     : (VGF,SI,SI)  -> VGF
++ expPot(v,e,d) returns the sum from \spad{i = 0} to
++ \spad{e - 1} of \spad{v**(q**i*d)}, interpreting
++ v as an element of a normal basis field and where q is
++ the size of the ground field.
++ Note that for a description of the algorithm, see
++ T.Itoh and S.Tsujii,
++ "A fast algorithm for computing multiplicative inverses in GF(2^m)
++ using normal bases",
++ Information and Computation 78, pp.171-177, 1988.
qPot       : (VGF,I)      -> VGF
++ qPot(v,e) computes \spad{v**(q**e)}, interpreting v as an element of
++ normal basis field, q the size of the ground field.
++ This is done by a cyclic e-shift of the vector v.

++ Basic Functions:
++ Related Constructors:
++ Also See:
++ AMS Classifications:
++ Keywords:
++ References:
++ Description:
++ This is an internal package
++ for computing approximate solutions to systems of polynomial equations.
++ The parameter K specifies the coefficient field of the input polynomials
++ and must be either \spad{Fraction(Integer)} or
++ \spad{Complex(Fraction Integer)}.
++ The parameter F specifies where the solutions must lie and can
++ be one of the following: \spad{Float}, \spad{Fraction(Integer)},
++ \spad{Complex(Float)},
++ \spad{Complex(Fraction Integer)}. The last parameter specifies the type
++ of the precision operand and must be either \spad{Fraction(Integer)} or
++ \spad{Float}.

— IntegerCombinatoricFunctions.help —

=====

IntegerCombinatoricFunctions examples

=====

The binomial(n, r) returns the number of subsets of r objects  
taken among n objects, i.e.  $n!/(r! * (n-r)!)$

The binomial coefficients are the coefficients of the series expansion  
of a power of a binomial, that is

n

```

--+    / n \    k          n
>    |      | x    = (1 + x)
--+    \ k /
k= 0

```

This leads to the famous pascal triangle. First we expose the `OutputForm` domain, which is normally hidden, so we can use it to format the lines.

```
)set expose add constructor OutputForm
```

Next we define a function that will output the list of binomial coefficients right justified with proper spacing:

```
pascalRow(n) == [right(binomial(n,i),4) for i in 0..n]
```

and now we format the whole line so that it looks centered:

```
displayRow(n)==output center blankSeparate pascalRow(n)
```

and we compute the triangle

```
for i in 0..7 repeat displayRow i
```

giving the pretty result:

```

Compiling function pascalRow with type NonNegativeInteger -> List
  OutputForm
Compiling function displayRow with type NonNegativeInteger -> Void

```

```

      1
     1 1
    1 2 1
   1 3 3 1
  1 4 6 4 1
 1 5 10 10 5 1
1 6 15 20 15 6 1
1 7 21 35 35 21 7 1

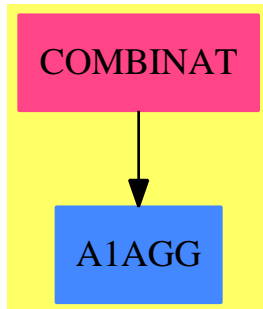

```

### 10.25.3 PollardSmallFactor

This is Brent's[?] optimization of Pollard's[?] rho factoring. Brent's algorithm is about 24 percent faster than Pollard's. Pollard's algorithm has complexity  $O(p^{1/2})$  where  $p$  is the smallest prime factor of the composite number  $N$ .

Pollard's idea is based on the observation that two numbers  $x$  and  $y$  are congruent modulo  $p$  with probability 0.5 after  $1.177 * \sqrt{p}$  numbers have been randomly chosen. If we try to factor  $n$  and  $p$  is a factor of  $n$ , then

$$1 < \gcd(|x - y|, n) \leq n$$

since  $p$  divides both  $|x - y|$  and  $n$ .

Given a function  $f$  which generates a pseudo-random sequence of numbers we allow  $x$  to walk the sequence in order and  $y$  to walk the sequence at twice the rate. At each cycle we compute  $\gcd(|x - y|, n)$ . If this GCD ever equals  $n$  then  $x = y$  which means that we have walked "all the way around the pseudo-random cycle" and we terminate with failure.

This algorithm returns failure on all primes but also fails on some composite numbers.

Quoting Brent's back-tracking idea:

The best-known algorithm for finding GCDs is the Euclidean algorithm which takes  $O(\log N)$  times as long as one multiplication mod  $N$ . Pollard showed that most of the GCD computations in Floyd's algorithm could be dispensed with.

... The idea is simple: if  $P_F$  computes  $GCD(z_1, N)$ ,  $GCD(z_2, N)$ , ..., then we compute

$$q_i = \prod_{j=1}^i z_j \pmod{N}$$

and only compute  $GCD(q_i, N)$  when  $i$  is a multiple of  $m$ , where  $\log N \ll m \ll N^{1/4}$ . Since  $q_{i+1} = q_i \times z_{i+1} \pmod{N}$ , the work required for each GCD computation in algorithm  $P_F$  is effectively reduced to that for a multiplication mod  $N$  in the modified algorithm. The probability of the algorithm failing because  $q_i = 0$  increases, so it is best not to choose  $m$  too large. This problem can be minimized by backtracking to the state after the previous GCD computation and setting  $m = 1$ .

Brent incorporates back-tracking, omits the random choice of  $u$ , and makes some minor modifications. His algorithm (p192-183) reads:

```

y := x0; r := 1; q := 1;
repeat x := y;
  for i := 1 to r do y := f(y); k := 0;
  repeat ys := y;
    for i := 1 to min(m, r - k) do
      begin y := f(y); q := q * |x - y| mod N
      end;
    G := GCD(q, N); k := k + m
  until (k ≥ r) or (G > 1); r := 2 * r
until G > 1;
if G = N then
  repeat ys := f(ys); G := GCD(|y - yx|, N)
  until G > 1;
if G = N then failure else success

```

Here we use the function

$$(y * y + 5 :: I) \text{ rem } n$$

as our pseudo-random sequence with a random starting value for  $y$ .

One possible optimization to explore is to keep a hash table for the computed values of the function  $y_{i+1} := f(y_i)$  since we effectively walk the sequence several times. And we walk the sequence in a loop many times. But because we are generating a very large number of numbers the array can be a simple array of fixed size that captures the last  $n$  values. So if we make a fixed array  $F$  of, say  $2^q$  elements we can store  $f(y_i)$  in  $F[y_i \bmod 2^q]$ .

One property that this algorithm assumes is that the function used to generate the numbers has a long, hopefully complete, period. It is not clear that the recommended function has that property.

— package INTFACT IntegerFactorizationPackage —

```
PollardSmallFactor(n:I):Union(I,"failed") ==
-- Use the Brent variation
x0 := random()$I
m := 100::I
y := x0 rem n
r:I := 1
q:I := 1
G:I := 1

G=n => "failed"
G
```

#### 10.25.4 BasicSieve

We create a list of prime numbers up to the limit given. The prior code used a circular list but tests of that list show that on average more than 50% of the required prime numbers. Overall this is a small percentage of the time needed to factor.

This loop uses three pieces of information

1. n which is the number we are testing
2. d which is the current prime to test
3. lim which is the upper limit of the primes to test

We loop d over the list of primes. If the remaining number n is smaller than the square of d then n must be prime and if it is not one, we add it to the list of primes. If the remaining

number is larger than the square of  $d$  we remove all factors of  $d$ , reducing  $n$  each time. Then we add a record of the new factor and its multiplicity,  $m$ . We continue the loop until we run out of primes.

Annoyingly enough, `primes` does not return an ordered list so we fix this.

The sieve works up to a given limit, reducing out the factors that it finds. If it can find all of the factors than it returns a factored result where the first element is the unit 1. If there is still a part of the number unfactored it returns the number and a list of the factors found and their multiplicity.

Basically we just loop thru the prime factors checking to see if they are a component of the number,  $n$ . If so, we remove the factor from the number  $n$  (possibly  $m$  times) and continue thru the list of primes.

— package INTFACT IntegerFactorizationPackage —

```
BasicSieve(n, lim) ==
  p:=primes(1::I,lim::I)$IntegerPrimesPackage(I)
  l:List(I) := append([first p],reverse rest p)
  ls := empty()$List(FFE)
  for d in l repeat
    if n<d*d then
      if n>1 then ls := concat_!(ls, ["prime",n,1]$FFE)
      return makeFR(1, ls)
    for m in 0.. while zero?(n rem d) repeat n := n quo d
    if m>0 then ls := concat_!(ls, ["prime",d,convert m]$FFE)
  makeFR(n,ls)
```

—————

### 10.25.5 BasicMethod

— package INTFACT IntegerFactorizationPackage —

```
BasicMethod n ==
  u:I
  if n<0 then (m := -n; u := -1)
  else (m := n; u := 1)
  x := BasicSieve(m, 1 + approxSqrt m)
  makeFR(u, factorList x)
```

—————

### 10.25.6 factor

The factor function is many orders of magnitude slower than the results of other systems. A posting on sci.math.symbolic showed that NTL could factor the final value (t6) in about 11 seconds. Axiom takes about 8 hours.

```

a1:=101
a2:=109
t1:=a1*a2
factor t1

a3:=21525175387
t2:=t1*a3
factor t2

a4:=218301576858349
t3:=t2*a4
factor t3

a5:=13731482973783137
t4:=t3*a5
factor t4

a6:=23326138687706820109
t5:=t4*a6
factor t5

a7:=4328240801173188438252813716944518369161
t6:=t5*a7
factor t6

```

— package INTFACT IntegerFactorizationPackage —

```

factor m ==
  u:I
  zero? m => 0
  if negative? m then (n := -m; u := -1)
                      else (n := m; u := 1)

=====

IntegerLinearDependence examples

=====

The elements  $v_1, \dots, v_N$  of a module  $M$  over a ring  $R$  are said to be linearly dependent over  $R$  if there exist  $c_1, \dots, c_N$  in  $R$ , not all 0, such that  $c_1 v_1 + \dots + c_N v_N = 0$ . If such  $c_i$ 's exist, they form what is called a linear dependence relation over  $R$  for the  $v_i$ 's.

The package IntegerLinearDependence provides functions for testing whether some elements of a module over the integers are linearly dependent over the integers, and to find the linear dependence relations, if any.

Consider the domain of two by two square matrices with integer entries.

```

M := SQMATRIX(2,INT)
SquareMatrix(2,Integer)

```

Type: Domain

Now create three such matrices.

```
m1: M := squareMatrix matrix [ [1, 2], [0, -1] ]
      +1  2 +
      |    |
      +0  - 1+
```

Type: SquareMatrix(2,Integer)

```
m2: M := squareMatrix matrix [ [2, 3], [1, -2] ]
      +2  3 +
      |    |
      +1  - 2+
```

Type: SquareMatrix(2,Integer)

```
m3: M := squareMatrix matrix [ [3, 4], [2, -3] ]
      +3  4 +
      |    |
      +2  - 3+
```

Type: SquareMatrix(2,Integer)

This tells you whether m1, m2 and m3 are linearly dependent over the integers.

```
linearlyDependentOverZ? vector [m1, m2, m3]
true
```

Type: Boolean

Since they are linearly dependent, you can ask for the dependence relation.

```
c := linearDependenceOverZ vector [m1, m2, m3]
      [1,- 2,1]
```

Type: Union(Vector Integer,...)

This means that the following linear combination should be 0.

```
c.1 * m1 + c.2 * m2 + c.3 * m3
      +0  0+
      |    |
      +0  0+
```

Type: SquareMatrix(2,Integer)

When a given set of elements are linearly dependent over R, this also means that at least one of them can be rewritten as a linear combination of the others with coefficients in the quotient field of R.

To express a given element in terms of other elements, use the operation solveLinearlyOverQ.

```
solveLinearlyOverQ(vector [m1, m3], m2)
```

```

1 1
[-,-]
2 2

```

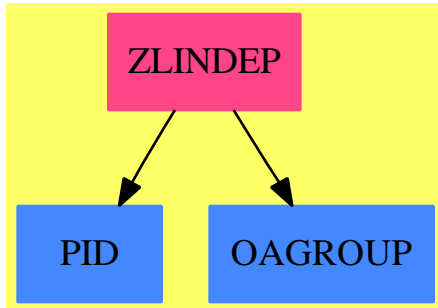

```
Type: Union(Vector Fraction Integer,...)
```

— IntegerNumberTheoryFunctions.help —

```
=====
IntegerNumberTheoryFunctions examples
=====
```

The IntegerNumberTheoryFunctions package contains a variety of operations of interest to number theorists. Many of these operations deal with divisibility properties of integers. (Recall that an integer  $a$  divides an integer  $b$  if there is an integer  $c$  such that  $b = a * c$ .)

The operation `divisors` returns a list of the divisors of an integer.

```
div144 := divisors(144)
      [1,2,3,4,6,8,9,12,16,18,24,36,48,72,144]
                        Type: List Integer
```

You can now compute the number of divisors of 144 and the sum of the divisors of 144 by counting and summing the elements of the list we just created.

```
 #(div144)
    15
                        Type: PositiveInteger
```

```
 reduce(+,div144)
    403
                        Type: PositiveInteger
```

Of course, you can compute the number of divisors of an integer  $n$ , usually denoted  $d(n)$ , and the sum of the divisors of an integer  $n$ , usually denoted  $\sigma(n)$ , without ever listing the divisors of  $n$ .

In Axiom, you can simply call the operations `numberOfDivisors` and `sumOfDivisors`.

```
 numberOfDivisors(144)
    15
                        Type: PositiveInteger
```

```
 sumOfDivisors(144)
    403
                        Type: PositiveInteger
```

The key is that  $d(n)$  and  $\sigma(n)$  are "multiplicative functions." This means that when  $n$  and  $m$  are relatively prime, that is, when  $n$  and  $m$  have no prime factor in common, then  $d(nm) = d(n) d(m)$  and  $\sigma(nm) = \sigma(n) \sigma(m)$ . Note that these functions are trivial to compute when  $n$  is a prime power and are computed for general  $n$  from the prime factorization of  $n$ . Other examples of multiplicative functions are  $\sigma_k(n)$ , the sum of the  $k$ -th powers of the divisors of  $n$  and  $\varphi(n)$ , the number of integers between 1 and  $n$  which are prime to  $n$ . The corresponding Axiom operations are called `sumOfKthPowerDivisors` and `eulerPhi`.

An interesting function is  $\mu(n)$ , the Moebius  $\mu$  function, defined as follows:  $\mu(1) = 1$ ,  $\mu(n) = 0$ , when  $n$  is divisible by a square, and  $\mu = (-1)^k$ , when  $n$  is the product of  $k$  distinct primes. The corresponding Axiom operation is `moebiusMu`. This function occurs in the following theorem:

Theorem: (Moebius Inversion Formula):

Let  $f(n)$  be a function on the positive integers and let  $F(n)$  be defined by

$$F(n) = \sum_{d|n} f(d)$$
the sum of  $f(n)$  over  $d|n$  where the sum is taken over the positive divisors of  $n$ . Then the values of  $f(n)$  can be recovered from the values of  $F(n)$ :  $f(n) = \sum_{d|n} \mu(d) F(n/d)$  where again the sum is taken over the positive divisors of  $n$ .

When  $f(n) = 1$ , then  $F(n) = d(n)$ . Thus, if you sum  $\mu(d) \dots d(n/d)$  over the positive divisors  $d$  of  $n$ , you should always get 1.

```
f1(n)==reduce(+,[moebiusMu(d)*numberOfDivisors(quo(n,d))_
for d in divisors(n)])
```

Type: Void

```
f1(200)
```

```
1
```

Type: PositiveInteger

```
f1(846)
```

```
1
```

Type: PositiveInteger

Similarly, when  $f(n) = n$ , then  $F(n) = \sigma(n)$ . Thus, if you sum  $\mu(d) \dots \sigma(n/d)$  over the positive divisors  $d$  of  $n$ , you should always get  $n$ .

```
f2(n) == reduce(+,[moebiusMu(d) * sumOfDivisors(quo(n,d))_
for d in divisors(n)])
```

Type: Void

```
f2(200)
```

```
200
```

Type: PositiveInteger

```
f2(846)
846
```

Type: PositiveInteger

The Fibonacci numbers are defined by

```
F(1) = F(2) = 1 and
F(n) = F(n-1) + F(n-2) for n = 3,4,...
```

The operation `fibonacci` computes the  $n$ -th Fibonacci number.

```
fibonacci(25)
75025
```

Type: PositiveInteger

```
[fibonacci(n) for n in 1..15]
[1,1,2,3,5,8,13,21,34,55,89,144,233,377,610]
```

Type: List Integer

Fibonacci numbers can also be expressed as sums of binomial coefficients.

```
fib(n) == reduce(+,[binomial(n-1-k,k) for k in 0..quo(n-1,2)])
```

Type: Void

```
fib(25)
75025
```

Type: PositiveInteger

```
[fib(n) for n in 1..15]
[1,1,2,3,5,8,13,21,34,55,89,144,233,377,610]
```

Type: List Integer

Quadratic symbols can be computed with the operations `legendre` and `jacobi`. The Legendre symbol  $a/p$  is defined for integers  $a$  and  $p$  with  $p$  an odd prime number. By definition,

```
(a/p) = +1, when a is a square (mod p),
(a/p) = -1, when a is not a square (mod p), and
(a/p) = 0, when a is divisible by p.
```

You compute  $(a/p)$  via the command `legendre(a,p)`.

```
legendre(3,5)
- 1
```

Type: Integer

```
legendre(23,691)
- 1
```

Type: Integer

The Jacobi symbol  $(a/n)$  is the usual extension of the Legendre symbol, where  $n$  is an arbitrary integer. The most important property of the Jacobi symbol is the following: if  $K$  is a quadratic field with discriminant  $d$  and quadratic character  $\chi$ , then  $\chi(n) = (d/n)$ . Thus, you can use the Jacobi symbol to compute, say, the class numbers of imaginary quadratic fields from a standard class number formula.

This function computes the class number of the imaginary quadratic field with discriminant  $d$ .

```
h(d) == quo(reduce(+,[jacobi(d,k) for k in 1..quo(-d, 2)]),2-jacobi(d,2))
Type: Void
```

```
h(-163)
1
Type: PositiveInteger
```

```
h(-499)
3
Type: PositiveInteger
```

```
h(-1832)
26
Type: PositiveInteger
```

```
=====
The inverse function
=====
```

The inverse function is derived from the Extended Euclidean Algorithm. If we divide one integer by another nonzero integer we get an integer quotient plus a remainder which is, in general, a rational number. For instance,

$$13/5 = 2 + 3/5$$

where 2 is the quotient and 3/5 is the remainder.

If we multiply thru by the denominator of the remainder we get an answer in integer terms which no longer involves division:

$$13 = 2(5) + 3$$

This gives a method of dividing integers. Specifically, if  $a$  and  $b$  are positive integers, there exist unique non-negative integers  $q$  and  $r$  so that

$$a = qb + r, \text{ where } 0 \leq r < b$$

$q$  is called the quotient and  $r$  the remainder.

The greatest common divisor of integers  $a$  and  $b$ , denoted by  $\gcd(a,b)$ , is the largest integer that divides (without remainder) both  $a$  and  $b$ . So, for example:

$\gcd(15, 5) = 5,$   
 $\gcd(7, 9) = 1,$   
 $\gcd(12, 9) = 3,$   
 $\gcd(81, 57) = 3.$

The gcd of two integers can be found by repeated application of the division algorithm, this is known as the Euclidean Algorithm. You repeatedly divide the divisor by the remainder until the remainder is 0. The gcd is the last non-zero remainder in this algorithm. The following example shows the algorithm.

Finding the gcd of 81 and 57 by the Euclidean Algorithm:

$81 = 1(57) + 24$   
 $57 = 2(24) + 9$   
 $24 = 2(9) + 6$   
 $9 = 1(6) + 3$   
 $6 = 2(3) + 0$

So the greatest common divisor, the  $\text{GCD}(81, 57) = 3$ .

If the  $\gcd(a, b) = r$  then there exist integers  $s$  and  $t$  so that

$$s(a) + t(b) = r$$

By back substitution in the steps in the Euclidean Algorithm, it is possible to find these integers  $s$  and  $t$ . We shall do this with the above example:

Starting with the next to last line, we have:

$$3 = 9 - 1(6)$$

From the line before that, we see that  $6 = 24 - 2(9)$ , so:

$$3 = 9 - 1(24 - 2(9)) = 3(9) - 1(24)$$

From the line before that, we have  $9 = 57 - 2(24)$ , so:

$$3 = 3(57 - 2(24)) - 1(24) = 3(57) - 7(24)$$

And, from the line before that  $24 = 81 - 1(57)$ , giving us:

$$3 = 3(57) - 7(81 - 1(57)) = 10(57) - 7(81)$$

So we have found  $s = -7$  and  $t = 10$ .

The Extended Euclidean Algorithm computes the  $\text{GCD}(a, b)$  and the values for  $s$  and  $t$ .

Suppose we were doing arithmetics modulo 26 and we needed to find the

inverse of a number mod 26. This turned out to be a difficult task (and not always possible). We observed that a number  $x$  had an inverse mod 26 (i.e., a number  $y$  so that  $xy = 1 \pmod{26}$ ) if and only if  $\gcd(x, 26) = 1$ . In the general case the inverse of  $x$  exists if and only if  $\gcd(x, n) = 1$  and if it exists then there exist integers  $s$  and  $t$  so that

$$sx + tn = 1$$

But this says that  $sx = 1 + (-t)n$ , or in other words,

$$sx \equiv 1 \pmod{n}$$

So,  $s$  (reduced mod  $n$  if need be) is the inverse of  $x$  mod  $n$ . The extended Euclidean algorithm calculates  $s$  efficiently.

```
=====
Finding the inverse mod n
=====
```

We will number the steps of the Euclidean algorithm starting with step 0. The quotient obtained at step  $i$  will be denoted by  $q_i$  and an auxiliary number,  $s_i$ . For the first two steps, the value of this number is given:

$$\begin{aligned} s(0) &= 0 \text{ and} \\ s(1) &= 1. \end{aligned}$$

For the remainder of the steps, we recursively calculate

$$s(i) = s(i-2) - s(i-1) q(i-2) \pmod{n}$$

The algorithm starts by "dividing"  $n$  by  $x$ . If the last non-zero remainder occurs at step  $k$ , then if this remainder is 1,  $x$  has an inverse and it is  $s(k+2)$ . If the remainder is not 1, then  $x$  does not have an inverse.

For example, find the inverse of 15 mod 26.

```
Step 0: 26 = 1(15) + 11 s(0) = 0
Step 1: 15 = 1(11) + 4 s(1) = 1
Step 2: 11 = 2(4) + 3 s(2) = 0 - 1( 1) mod 26 = 25
Step 3: 4 = 1(3) + 1 s(3) = 1 - 25( 1) mod 26 = -24 mod 26 = 2
Step 4: 3 = 3(1) + 0 s(4) = 25 - 2( 2) mod 26 = 21
          s(5) = 2 - 21( 1) mod 26 = -19 mod 26 = 7
```

Notice that  $15(7) = 105 = 1 + 4(26) \equiv 1 \pmod{26}$ .

Using the half extended Euclidean algorithm we compute  $1/a \pmod{b}$ .

```
inverse:(INT,INT)->INT
                                     Type: Void

Type: PositiveInteger

=====

The Chinese Remainder Algorithm

=====

The Chinese Remainder Theorem says that given  $n$  moduli  $m_i$  for  $(1 \leq i \leq n)$  of pairwise coprime integers and a set of congruential equations  $x \equiv c_i \pmod{m_i}$   $(1 \leq i \leq n)$  for an arbitrary integer  $x$ , there is a unique solution  $c$  for  $x$  modulo the product  $M = \prod_{i=1}^n m_i$ , say  $x \equiv c \pmod{M}$ .

If the upper bound  $B$  of the absolute value of  $x$  is known, that is, if  $|x| \leq B$  then the number of moduli can be chosen such that  $B < M/2$ . If  $c$  is the absolutely least residue modulo  $M$  then  $c$  and  $x$  coincide so  $x$  is uniquely determined.

Let  $m_1, m_2, \dots, m_r$  be positive integers that are pairwise relatively prime. Let  $x_1, x_2, \dots, x_r$  be integers with  $0 \leq x_i < m_i$ . Then, there is exactly one  $x$  in the interval  $0 \leq x < m_1 \dots m_2 \dots m_r$  that satisfies the remainder equations

$$\text{irem}(x, m_i) = x_i, \quad i=1, 2, \dots, r$$

where  $\text{irem}$  is the positive integer remainder function.

For example, let  $x_1 = 4$ ,  $m_1 = 5$ ,  $x_2 = 2$ ,  $m_2 = 3$ . We know that  $\text{irem}(x, m_1) = x_1$

```

irem(x,m2) = x2
where 0 <= x_ < m1 and 0 <= x2 < m2.

```

By the extended Euclidean Algorithm there are integers  $c$  and  $d$  such that

$$c m_1 + d m_2 = 1$$

In this case we are looking for an integer such that

$$\begin{aligned} \text{irem}(x,5) &= 4, \\ \text{irem}(x,3) &= 2 \end{aligned}$$

The algorithm we use is to first compute the positive integer remainder of  $x_1$  and  $m_1$  to get a new  $x_1$ :

```

x1 = positiveRemainder(x1,m1)
4 = positiveRemainder(4,5)

```

Next compute the positive integer remainder of  $x_2$  and  $m_2$  to get a new  $x_2$ :

```

x2 = positiveRemainder(x2,m2)
2 = positiveRemainder(2,3)

```

Then we compute  $x_1 + m_1 \dots \text{positiveRemainder}(((x_2-x_1)*\text{inverse}(m_1,m_2)),m_2)$

```

or
4+5*positiveRemainder(((2-4)*inverse(5,3)),3)
or
4+5*positiveRemainder(-2*2),3)
or
4+5*2
or
14

```

This function has a restricted signature which only allows for computing the chinese remainder of two numbers and two moduli.

bernoulli : I -> RN
  ++ \spad{bernoulli(n)} returns the nth Bernoulli number.
  ++ this is \spad{B(n,0)}, where \spad{B(n,x)} is the \spad{n}th Bernoulli
  ++ polynomial.
chineseRemainder: (I,I,I,I) -> I
  ++ \spad{chineseRemainder(x1,m1,x2,m2)} returns w, where w is such that
  ++ \spad{w = x1 mod m1} and \spad{w = x2 mod m2}. Note that \spad{m1} and
  ++ \spad{m2} must be relatively prime.
divisors : I -> List I
  ++ \spad{divisors(n)} returns a list of the divisors of n.
euler : I -> I
  ++ \spad{euler(n)} returns the \spad{n}th Euler number. This is
  ++ \spad{2^n E(n,1/2)}, where \spad{E(n,x)} is the nth Euler polynomial.
eulerPhi : I -> I
  ++ \spad{eulerPhi(n)} returns the number of integers between 1 and n
  ++ (including 1) which are relatively prime to n. This is the Euler phi
  ++ function \spad{\phi(n)} is also called the totient function.
fibonacci : I -> I
  ++ \spad{fibonacci(n)} returns the nth Fibonacci number. the Fibonacci
  ++ numbers \spad{F[n]} are defined by \spad{F[0] = F[1] = 1} and
  ++ \spad{F[n] = F[n-1] + F[n-2]}.
  ++ The algorithm has running time \spad{O(log(n)^3)}.
  ++ Reference: Knuth, The Art of Computer Programming
  ++ Vol 2, Semi-Numerical Algorithms.
harmonic : I -> RN
  ++ \spad{harmonic(n)} returns the nth harmonic number. This is
  ++ \spad{H[n] = sum(1/k,k=1..n)}.
jacobi : (I,I) -> I
  ++ \spad{jacobi(a,b)} returns the Jacobi symbol \spad{J(a/b)}.
  ++ When b is odd, \spad{J(a/b) = product(L(a/p) for p in factor b )}.
  ++ Note that by convention, 0 is returned if \spad{gcd(a,b) != 1}.
  ++ Iterative \spad{O(log(b)^2)} version coded by Michael Monagan June 1987.
legendre : (I,I) -> I
  ++ \spad{legendre(a,p)} returns the Legendre symbol \spad{L(a/p)}.
  ++ \spad{L(a/p) = (-1)**((p-1)/2) mod p} (p prime), which is 0 if \spad{a}
  ++ is 0, 1 if \spad{a} is a quadratic residue \spad{mod p} and -1 otherwise.
  ++ Note that because the primality test is expensive,
  ++ if it is known that p is prime then use \spad{jacobi(a,p)}.
moebiusMu : I -> I
  ++ \spad{moebiusMu(n)} returns the Moebius function \spad{\mu(n)}.
  ++ \spad{\mu(n)} is either -1,0 or 1 as follows:
  ++ \spad{\mu(n) = 0} if n is divisible by a square > 1,
  ++ \spad{\mu(n) = (-1)^k} if n is square-free and has k distinct
  ++ prime divisors.
numberOfDivisors: I -> I
  ++ \spad{numberOfDivisors(n)} returns the number of integers between 1 and n
  ++ (inclusive) which divide n. The number of divisors of n is often
  ++ denoted by \spad{\tau(n)}.
sumOfDivisors : I -> I
  ++ \spad{sumOfDivisors(n)} returns the sum of the integers between 1 and n

```

```

++ (inclusive) which divide n. The sum of the divisors of n is often
++ denoted by \spad{sigma(n)}.
sumOfKthPowerDivisors: (I,NNI) -> I
++ \spad{sumOfKthPowerDivisors(n,k)} returns the sum of the \spad{k}th
++ powers of the integers between 1 and n (inclusive) which divide n.
++ the sum of the \spad{k}th powers of the divisors of n is often denoted
++ by \spad{sigma_k(n)}.

## 10.28 package PRIMES IntegerPrimesPackage

We've expanded the list of small primes to include those between 1 and 10000.

### 10.28.1 IntegerPrimesPackage (PRIMES)

#### Exports:

nextPrime prevPrime prime? primes

— package PRIMES IntegerPrimesPackage —

```
)abbrev package PRIMES IntegerPrimesPackage
++ Author: Michael Monagan
++ Date Created: August 1987
++ Date Last Updated: 31 May 1993
++ Updated by: James Davenport
++ Updated Because: of problems with strong pseudo-primes
++ and for some efficiency reasons.
++ Basic Operations:
++ Related Domains:
++ Also See:
++ AMS Classifications:
++ Keywords: integer, prime
++ Examples:
++ References: Davenport's paper in ISSAC 1992
++             AXIOM Technical Report ATR/6
++ Description:
++ The \spadtype{IntegerPrimesPackage} implements a modification of
++ Rabin's probabilistic
++ primality test and the utility functions \spadfun{nextPrime},
++ \spadfun{prevPrime} and \spadfun{primes}.

IntegerPrimesPackage(I:IntegerNumberSystem): with
  prime?: I -> Boolean
    ++ \spad{prime?(n)} returns true if n is prime and false if not.
    ++ The algorithm used is Rabin's probabilistic primality test
    ++ (reference: Knuth Volume 2 Semi Numerical Algorithms).
    ++ If \spad{prime? n} returns false, n is proven composite.
    ++ If \spad{prime? n} returns true, prime? may be in error
    ++ however, the probability of error is very low.
    ++ and is zero below 25*10**9 (due to a result of Pomerance et al),
```

```

++ below 10**12 and 10**13 due to results of Pinch,
++ and below 341550071728321 due to a result of Jaeschke.
++ Specifically, this implementation does at least 10 pseudo prime
++ tests and so the probability of error is \spad{< 4**(-10)}.
++ The running time of this method is cubic in the length
++ of the input n, that is \spad{O( (log n)**3 )}, for n<10**20.
++ beyond that, the algorithm is quartic, \spad{O( (log n)**4 )}.
++ Two improvements due to Davenport have been incorporated
++ which catches some trivial strong pseudo-primes, such as
++ [Jaeschke, 1991] 1377161253229053 * 413148375987157, which
++ the original algorithm regards as prime
nextPrime: I -> I
++ \spad{nextPrime(n)} returns the smallest prime strictly larger than n
prevPrime: I -> I
++ \spad{prevPrime(n)} returns the largest prime strictly smaller than n
primes: (I,I) -> List I
++ \spad{primes(a,b)} returns a list of all primes p with
++ \spad{a <= p <= b}
== add

```

## 10.28.2 smallPrimes

This is a table of all of the primes in [2..10000]. It is used by the prime? function to check for primality. It is used by the primes function to generate arrays of primes in a given range. Changing the range included in this table implies changing the value of the nextSmallPrime variable. There is a constant in the function squareFree from IntegerFactorizationPackage that is the square of the upper bound of the table range, in this case 10000000.

— package PRIMES IntegerPrimesPackage —

```

## 10.30 package IROOT IntegerRoots

### 10.30.1 IntegerRoots (IROOT)

#### Exports:

approxSqrt approxNthRoot perfectNthPower? perfectNthRoot perfectSqrt perfectSquare?

#### — package IROOT IntegerRoots —

```
)abbrev package IROOT IntegerRoots
++ Author: Michael Monagan
++ Date Created: November 1987
++ Date Last Updated:
++ Basic Operations:
++ Related Domains:
++ Also See:
++ AMS Classifications:
++ Keywords: integer roots
++ Examples:
++ References:
++ Description:
++ The \spadtype{IntegerRoots} package computes square roots and
++ nth roots of integers efficiently.

IntegerRoots(I:IntegerNumberSystem): Exports == Implementation where
  NNI ==> NonNegativeInteger

Exports ==> with
  perfectNthPower?: (I, NNI) -> Boolean
```

```

++ \spad{perfectNthPower?(n,r)} returns true if n is an \spad{r}th
++ power and false otherwise
perfectNthRoot: (I,NNI) -> Union(I,"failed")
++ \spad{perfectNthRoot(n,r)} returns the \spad{r}th root of n if n
++ is an \spad{r}th power and returns "failed" otherwise
perfectNthRoot: I -> Record(base:I, exponent:NNI)
++ \spad{perfectNthRoot(n)} returns \spad{[x,r]}, where \spad{n = x\^r}
++ and r is the largest integer such that n is a perfect \spad{r}th power
approxNthRoot: (I,NNI) -> I
++ \spad{approxRoot(n,r)} returns an approximation x
++ to \spad{n**(1/r)} such that \spad{-1 < x - n**(1/r) < 1}
perfectSquare?: I -> Boolean
++ \spad{perfectSquare?(n)} returns true if n is a perfect square
++ and false otherwise
perfectSqrt: I -> Union(I,"failed")
++ \spad{perfectSqrt(n)} returns the square root of n if n is a
++ perfect square and returns "failed" otherwise
approxSqrt: I -> I
++ \spad{approxSqrt(n)} returns an approximation x
++ to \spad{sqrt(n)} such that \spad{-1 < x - sqrt(n) < 1}.
++ Compute an approximation s to \spad{sqrt(n)} such that
++ \spad{-1 < s - sqrt(n) < 1}
++ A variable precision Newton iteration is used.
++ The running time is \spad{O( log(n)**2 )}.

Implementation ==> add
import IntegerPrimesPackage(I)

resMod144: List I := [0::I,1::I,4::I,9::I,16::I,25::I,36::I,49::I,
52::I,64::I,73::I,81::I,97::I,100::I,112::I,121::I]

++ Keywords: integral basis, function field, number field
++ Examples:
++ References:
++ Description:
++ This package contains functions used in the packages
++ FunctionFieldIntegralBasis and NumberFieldIntegralBasis.

IntegralBasisTools(R,UP,F): Exports == Implementation where
  R  : EuclideanDomain with
      squareFree: $ -> Factored $
      ++ squareFree(x) returns a square-free factorisation of x
  UP : UnivariatePolynomialCategory R
  F   : FramedAlgebra(R,UP)
  Mat ==> Matrix R
```

```

NNI ==> NonNegativeInteger
Ans ==> Record(basis: Mat, basisDen: R, basisInv:Mat)

Exports ==> with

diagonalProduct: Mat -> R
  ++ diagonalProduct(m) returns the product of the elements on the
  ++ diagonal of the matrix m
matrixGcd: (Mat,R,NNI) -> R
  ++ matrixGcd(mat,sing,n) is \spad{gcd(sing,g)} where \spad{g} is the
  ++ gcd of the entries of the \spad{n}-by-\spad{n} upper-triangular
  ++ matrix \spad{mat}.
divideIfCan_!: (Matrix R,Matrix R,R,Integer) -> R
  ++ divideIfCan!(matrix,matrixOut,prime,n) attempts to divide the
  ++ entries of \spad{matrix} by \spad{prime} and store the result in
  ++ \spad{matrixOut}. If it is successful, 1 is returned and if not,
  ++ \spad{prime} is returned. Here both \spad{matrix} and
  ++ \spad{matrixOut} are \spad{n}-by-\spad{n} upper triangular matrices.
leastPower: (NNI,NNI) -> NNI
  ++ leastPower(p,n) returns e, where e is the smallest integer
  ++ such that \spad{p **e >= n}
idealiser: (Mat,Mat) -> Mat
  ++ idealiser(m1,m2) computes the order of an ideal defined by m1 and m2
idealiser: (Mat,Mat,R) -> Mat
  ++ idealiser(m1,m2,d) computes the order of an ideal defined by m1 and m2
  ++ where d is the known part of the denominator
idealiserMatrix: (Mat, Mat) -> Mat
  ++ idealiserMatrix(m1, m2) returns the matrix representing the linear
  ++ conditions on the Ring associated with an ideal defined by m1 and m2.
moduleSum: (Ans,Ans) -> Ans
  ++ moduleSum(m1,m2) returns the sum of two modules in the framed
  ++ algebra \spad{F}. Each module \spad{mi} is represented as follows:
  ++ F is a framed algebra with R-module basis \spad{w1,w2,...,wn} and
  ++ \spad{mi} is a record \spad{[basis,basisDen,basisInv]}. If
  ++ \spad{basis} is the matrix \spad{(aij, i = 1..n, j = 1..n)}, then
  ++ a basis \spad{v1,...,vn} for \spad{mi} is given by
  ++ \spad{vi} = (1/basisDen) * sum(aij * wj, j = 1..n)}, i.e. the
  ++ \spad{i}th row of 'basis' contains the coordinates of the
  ++ \spad{i}th basis vector. Similarly, the \spad{i}th row of the
  ++ matrix \spad{basisInv} contains the coordinates of \spad{wi} with
  ++ respect to the basis \spad{v1,...,vn}: if \spad{basisInv} is the
  ++ matrix \spad{(bij, i = 1..n, j = 1..n)}, then
  ++ \spad{wi} = sum(bij * vj, j = 1..n)}.

++ space W of V = <base>, such that for all G in W, the
++ divisor (G) >= D. All the elements in base must be homogeneous
++ polynomial of degree n. Typicaly, base is the set of all monomial
++ of degree n: in that case, interpolateForms(D,n,pol,base)
++ returns the basis of the vector space of all forms of degree d that
++ interpolated D. The argument pol must be the same polynomial that
++ defined the curve form which the divisor D is defined.

++ Description:
++ IrrRepSymNatPackage contains functions for computing
++ the ordinary irreducible representations of symmetric groups on
++ n letters {1,2,...,n} in Young's natural form and their dimensions.
++ These representations can be labelled by number partitions of n,
++ i.e. a weakly decreasing sequence of integers summing up to n, e.g.
++ [3,3,3,1] labels an irreducible representation for n equals 10.
++ Note that whenever a \spadtype{List Integer} appears in a signature,
++ a partition required.
-- NOT TRUE in current system, but should:
-- also could be an element of \spadtype{Partition}

=====

LazardSetSolvingPackage examples

=====

The LazardSetSolvingPackage package constructor solves polynomial systems by means of Lazard triangular sets. However one condition is relaxed: Regular triangular sets whose saturated ideals have positive dimension are not necessarily normalized.

The decompositions are computed in two steps. First the algorithm of Moreno Maza (implemented in the `RegularTriangularSet` domain constructor) is called. Then the resulting decompositions are converted into lists of square-free regular triangular sets and the redundant components are removed. Moreover, zero-dimensional regular triangular sets are normalized.

Note that the way of understanding triangular decompositions is detailed in the example of the `RegularTriangularSet` constructor.

The `LazardSetSolvingPackage` constructor takes six arguments. The first one, `R`, is the coefficient ring of the polynomials; it must belong to the category `GcdDomain`. The second one, `E`, is the exponent monoid of the polynomials; it must belong to the category `OrderedAbelianMonoidSup`. The third one, `V`, is the ordered set of variables; it must belong to the category `OrderedSet`. The fourth one is the polynomial ring; it must belong to the category `RecursivePolynomialCategory(R,E,V)`. The fifth one is a domain of the category `RegularTriangularSetCategory(R,E,V,P)` and the last one is a domain of the category `SquareFreeRegularTriangularSetCategory(R,E,V,P)`. The abbreviation for `LazardSetSolvingPackage` is `LAZM3PK`.

For the purpose of solving zero-dimensional algebraic systems, see also `LexTriangularPackage` and `ZeroDimensionalSolvePackage`. These packages are easier to call than `LAZM3PK`. Moreover, the `ZeroDimensionalSolvePackage` package provides operations to compute either the complex roots or the real roots.

We illustrate now the use of the `LazardSetSolvingPackage` package constructor with two examples (Butcher and Vermeer).

Define the coefficient ring.

```
R := Integer
  Integer
```

Define the list of variables,

```
ls : List Symbol := [b1,x,y,z,t,v,u,w]
  [b1,x,y,z,t,v,u,w]
```

and make it an ordered set:

```
V := OVAR(ls)
  OrderedVariableList [b1,x,y,z,t,v,u,w]
```

then define the exponent monoid.

```
E := IndexedExponents V
```

Define the polynomial ring.

```
P := NSMP(R, V)
```

Let the variables be polynomial.

```
b1: P := 'b1
```

```
x: P := 'x
```

```
y: P := 'y
```

```
z: P := 'z
```

```
t: P := 't
```

```
u: P := 'u
```

```
v: P := 'v
```

```
w: P := 'w
```

Now call the `{\tt RegularTriangularSet}` domain constructor.

```
T := REGSET(R,E,V,P)
```

Define a polynomial system (the Butcher example).

```
p0 := b1 + y + z - t - w
```

```
p1 := 2*z*u + 2*y*v + 2*t*w - 2*w**2 - w - 1
```

```
p2 := 3*z*u**2 + 3*y*v**2 - 3*t*w**2 + 3*w**3 + 3*w**2 - t + 4*w
```

```
p3 := 6*x*z*v - 6*t*w**2 + 6*w**3 - 3*t*w + 6*w**2 - t + 4*w
```

```
p4 := 4*z*u**3 + 4*y*v**3 + 4*t*w**3 - 4*w**4 - 6*w**3 + 4*t*w - 10*w**2 - w - 1
```

```
p5 := 8*x*z*u*v + 8*t*w**3 - 8*w**4 + 4*t*w**2 - 12*w**3 + 4*t*w - 14*w**2 - 3*w - 1
```

```
p6 := 12*x*z*v**2 + 12*t*w**3 - 12*w**4 + 12*t*w**2 - 18*w**3 + 8*t*w - 14*w**2 - w - 1
```

```
p7 := -24*t*w**3 + 24*w**4 - 24*t*w**2 + 36*w**3 - 8*t*w + 26*w**2 + 7*w + 1
```

```
lp := [p0, p1, p2, p3, p4, p5, p6, p7]
```

```
[b1 + y + z - t - w, 2v y + 2u z + 2w t - 2w - w - 1,
 2      2      2      3      2
 3v y + 3u z + (- 3w - 1)t + 3w + 3w + 4w,
 2      3      2
 6v z x + (- 6w - 3w - 1)t + 6w + 6w + 4w,
```

$$\begin{aligned}
& 4v^3y + 4u^3z + (4w^3 + 4w)t^4 - 4w^4 - 6w^3 - 10w^2 - w - 1, \\
& 8u^2vz + (8w^3 + 4w^2 + 4w)t^4 - 8w^4 - 12w^3 - 14w^2 - 3w - 1, \\
& 12v^2z + (12w^3 + 12w^2 + 8w)t^4 - 12w^4 - 18w^3 - 14w^2 - w - 1, \\
& (-24w^3 - 24w^2 - 8w)t^4 + 24w^4 + 36w^3 + 26w^2 + 7w + 1]
\end{aligned}$$

First of all, let us solve this system in the sense of Lazard by means of the REGSET constructor:

```

lts := zeroSetSplit(lp,false)$T
[{w + 1,u,v,t + 1,b1 + y + z + 2}, {w + 1,v,t + 1,z,b1 + y + 2},
 {w + 1,t + 1,z,y,b1 + 2}, {w + 1,v - u,t + 1,y + z,x,b1 + 2},
 {w + 1,u,t + 1,y,x,b1 + z + 2},

{144w^5 + 216w^4 + 96w^3 + 6w^2 - 11w - 1,
 (12w^2 + 9w + 1)u - 72w^5 - 108w^4 - 42w^3 - 9w^2 - 3w,
 (12w^2 + 9w + 1)v + 36w^4 + 54w^3 + 18w^2,
 (24w^3 + 24w^2 + 8w)t - 24w^4 - 36w^3 - 26w^2 - 7w - 1,

 (12u^2v - 12u^2)z + (12w^2v + 12w^2 + 4)t + (3w - 5)v + 36w^4 + 42w^3 + 6w^2
 + - 16w
 ,

 2v^2y + 2u^2z + 2w^2t - 2w^2 - w - 1,
 6v^2z + (-6w^2 - 3w - 1)t + 6w^3 + 6w^2 + 4w, b1 + y + z - t - w}
]

```

We can get the dimensions of each component of a decomposition as follows.

```

[coHeight(ts) for ts in lts]
[3,3,3,2,2,0]

```

The first five sets have a simple shape. However, the last one, which has dimension zero, can be simplified by using Lazard triangular sets.

Thus we call the SquareFreeRegularTriangularSet domain constructor,

```

ST := SREGSET(R,E,V,P)

```

and set the LAZM3PK package constructor to our situation.

```
pack := LAZM3PK(R,E,V,P,T,ST)
```

We are ready to solve the system by means of Lazard triangular sets:

```
zeroSetSplit(lp,false)$pack
[{w + 1,t + 1,z,y,b1 + 2}, {w + 1,v,t + 1,z,b1 + y + 2},
 {w + 1,u,v,t + 1,b1 + y + z + 2}, {w + 1,v - u,t + 1,y + z,x,b1 + 2},
 {w + 1,u,t + 1,y,x,b1 + z + 2},

      5      4      3      2      4      3      2
{144w  + 216w  + 96w  + 6w  - 11w - 1, u - 24w  - 36w  - 14w  + w + 1,
      4      3      2      4      3      2
 3v - 48w  - 60w  - 10w  + 8w + 2, t - 24w  - 36w  - 14w  - w + 1,
      4      3      2
 486z - 2772w  - 4662w  - 2055w  + 30w + 127,
      4      3      2
 2916y - 22752w  - 30312w  - 8220w  + 2064w + 1561,
      4      3      2
 356x - 3696w  - 4536w  - 968w  + 822w + 371,
      4      3      2
 2916b1 - 30600w  - 46692w  - 20274w  - 8076w + 593}
]
```

We see the sixth triangular set is nicer now: each one of its polynomials has a constant initial.

We follow with the Vermeer example. The ordering is the usual one for this system.

Define the polynomial system.

```
f0 := (w - v) ** 2 + (u - t) ** 2 - 1
```

$$t^2 - 2ut + v^2 - 2wv + u^2 + w^2 - 1$$

```
f1 := t ** 2 - v ** 3
```

$$t^2 - v^3$$

```
f2 := 2 * t * (w - v) + 3 * v ** 2 * (u - t)
```

$$(-3v^2 - 2v + 2w)t + 3uv^2$$

```

f3 := (3 * z * v ** 2 - 1) * (2 * z * t - 1)

      2 2      2
      6v t z  + (- 2t - 3v )z + 1

lf := [f0, f1, f2, f3]

      2      2      2      2      2      3      2      2
      [t  - 2u t + v  - 2w v + u  + w  - 1, t  - v , (- 3v  - 2v + 2w)t + 3u v ,
      2 2      2
      6v t z  + (- 2t - 3v )z + 1]

```

First of all, let us solve this system in the sense of Kalkbrener by means of the REGSET constructor:

```

zeroSetSplit(lf,true)$T
[
  {
    6      3      2      4
    729u  + (- 1458w  + 729w  - 4158w - 1685)u
  +
    6      5      4      3      2      2      8
    (729w  - 1458w  - 2619w  - 4892w  - 297w  + 5814w + 427)u  + 729w
  +
    7      6      5      4      3      2
    216w  - 2900w  - 2376w  + 3870w  + 4072w  - 1188w  - 1656w + 529
  ,
    4      3      2      2      6      5
    2187u  + (- 4374w  - 972w  - 12474w - 2868)u  + 2187w  - 1944w
  +

]

```

We have obtained one regular chain (i.e. regular triangular set) with dimension 1. This set is in fact a characterist set of the (radical of) the ideal generated by the input system lf. Thus we have only the generic points of the variety associated with lf (for the elimination ordering given by ls).

So let us get now a full description of this variety.

Hence, we solve this system in the sense of Lazard by means of the REGSET constructor:

```

zeroSetSplit(lf,false)$T
[

& 6t^2 - 2v - 3w^2 + 2w + 3, 3vz - 1\} \\
& ]
\end{aligned}$$

We retrieve our regular chain of dimension 1 and we get three regular chains of dimension 0 corresponding to the degenerated cases. We want now to simplify these zero-dimensional regular chains by using Lazard triangular sets. Moreover, this will allow us to prove that the above decomposition has no redundant component.

Generally, decompositions computed by the REGSET constructor do not have redundant components. However, to be sure that no redundant component occurs one needs to use the SREGSET or LAZM3PK constructors.

So let us solve the input system in the sense of Lazard by means of the LAZM3PK constructor:

$$\begin{aligned}
& \text{zeroSetSplit}(lf, false) \$ \text{pack} \\
& [ \\
& \{ \\
& 729u^6 + (-1458w^3 + 729w^2 - 4158w - 1685)u^4 \\
& + (729w^6 - 1458w^5 - 2619w^4 - 4892w^3 - 297w^2 + 5814w + 427)u^2 + 729w^8 \\
& + 216w^7 - 2900w^6 - 2376w^5 + 3870w^4 + 4072w^3 - 1188w^2 - 1656w + 529 \\
& , \\
& 2187u^4 + (-4374w^3 - 972w^2 - 12474w - 2868)u^2 + 2187w^6 - 1944w^5 \\
& + 10125w^4 - 4800w^3 + 2501w^2 + 4968w - 1587 \\
& \} \\
& ]
\end{aligned}$$

```

}
]
```

Due to square-free factorization, we obtained now four zero-dimensional regular chains. Moreover, each of them is normalized (the initials are constant). Note that these zero-dimensional components may be investigated further with the `ZeroDimensionalSolvePackage` package constructor.

++ Date Last Updated: 12/16/1998
++ Basic Functions:
++ Related Constructors:
++ Also See:
++ AMS Classifications:
++ Keywords:
++ References :
++ [1] D. LAZARD "A new method for solving algebraic systems of
++       positive dimension" Discr. App. Math. 33:147-160,1991
++ [2] M. MORENO MAZA "A new algorithm for computing triangular
++       decomposition of algebraic varieties" NAG Tech. Rep. 4/98.
++ Description:
++ A package for solving polynomial systems by means of Lazard triangular
++ sets. This package provides two operations. One for solving in the sense
++ of the regular zeros, and the other for solving in the sense of
++ the Zariski closure. Both produce square-free regular sets.
++ Moreover, the decompositions do not contain any redundant component.
++ However, only zero-dimensional regular sets are normalized, since
++ normalization may be time consuming in positive dimension.
++ The decomposition process is that of [2].

=====

LexTriangularPackage examples

=====

The LexTriangularPackage package constructor provides an implementation of the lexTriangular algorithm (D. Lazard "Solving Zero-dimensional Algebraic Systems", J. of Symbol. Comput., 1992). This algorithm decomposes a zero-dimensional variety into zero-sets of regular triangular sets. Thus the input system must have a finite number of complex solutions. Moreover, this system needs to be a lexicographical Groebner basis.

This package takes two arguments: the coefficient-ring  $R$  of the polynomials, which must be a GcdDomain and their set of variables given by  $ls$  a List Symbol. The type of the input polynomials must be `NewSparseMultivariatePolynomial(R,V)` where  $V$  is `OrderedVariableList(ls)`. The abbreviation for LexTriangularPackage is LEXTRIPK. The main operations are `lexTriangular` and `squareFreeLexTriangular`. The later provide decompositions by means of square-free regular triangular sets, built with the `SquareFreeRegularTriangularSet` constructor, whereas the former uses the `RegularTriangularSet` constructor. Note that these constructors also implement another algorithm for solving algebraic systems by means of regular triangular sets; in that case no computations of Groebner bases are needed and the input system may have any dimension (i.e. it may have an infinite number of solutions).

The implementation of the lexTriangular algorithm provided in the LexTriangularPackage constructor differs from that reported in "Computations of gcd over algebraic towers of simple extensions" by M. Moreno Maza and R. Rioboo (in proceedings of AAECC11, Paris, 1995). Indeed, the `squareFreeLexTriangular` operation removes all multiplicities of the solutions (i.e. the computed solutions are pairwise different) and the `lexTriangular` operation may keep some multiplicities; this

later operation runs generally faster than the former.

The interest of the lexTriangular algorithm is due to the following experimental remark. For some examples, a triangular decomposition of a zero-dimensional variety can be computed faster via a lexicographical Groebner basis computation than by using a direct method (like that of SquareFreeRegularTriangularSet and RegularTriangularSet). This happens typically when the total degree of the system relies essentially on its smallest variable (like in the Katsura systems). When this is not the case, the direct method may give better timings (like in the Rose system).

Of course, the direct method can also be applied to a lexicographical Groebner basis. However, the lexTriangular algorithm takes advantage of the structure of this basis and avoids many unnecessary computations which are performed by the direct method.

For this purpose of solving algebraic systems with a finite number of solutions, see also the ZeroDimensionalSolvePackage. It allows to use both strategies (the lexTriangular algorithm and the direct method) for computing either the complex or real roots of a system.

Note that the way of understanding triangular decompositions is detailed in the example of the RegularTriangularSet constructor.

Since the LexTriangularPackage package constructor is limited to zero-dimensional systems, it provides a zeroDimensional? operation to check whether this requirement holds. There is also a groebner operation to compute the lexicographical Groebner basis of a set of polynomials with type NewSparseMultivariatePolynomial(R,V). The elimination ordering is that given by ls (the greatest variable being the first element of ls). This basis is computed by the FLGM algorithm (Faugere et al. "Efficient Computation of Zero-Dimensional Groebner Bases by Change of Ordering", J. of Symbol. Comput., 1993) implemented in the LinGroebnerPackage package constructor.

Once a lexicographical Groebner basis is computed, then one can call the operations lexTriangular and squareFreeLexTriangular. Note that these operations admit an optional argument to produce normalized triangular sets. There is also a zeroSetSplit operation which does all the job from the input system; an error is produced if this system is not zero-dimensional.

Let us illustrate the facilities of the LexTriangularPackage constructor by a famous example, the cyclic-6 root system.

Define the coefficient ring.

```
R := Integer
Integer
```

Type: Domain

Define the list of variables,

```
ls : List Symbol := [a,b,c,d,e,f]
[a,b,c,d,e,f]
Type: List Symbol
```

and make it an ordered set.

```
V := OVAR(ls)
OrderedVariableList [a,b,c,d,e,f]
Type: Domain
```

Define the polynomial ring.

```
P := NSMP(R, V)
NewSparseMultivariatePolynomial(Integer, OrderedVariableList [a,b,c,d,e,f])
Type: Domain
```

Define the polynomials.

```
p1: P := a*b*c*d*e*f - 1
f e d c b a - 1
Type: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [a,b,c,d,e,f])
```

```
p2: P := a*b*c*d*e + a*b*c*d*f + a*b*c*e*f + a*b*d*e*f + a*c*d*e*f + b*c*d*e*f
(((e + f)d + f e)c + f e d)b + f e d c)a + f e d c b
Type: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [a,b,c,d,e,f])
```

```
p3: P := a*b*c*d + a*b*c*f + a*b*e*f + a*d*e*f + b*c*d*e + c*d*e*f
((d + f)c + f e)b + f e d)a + e d c b + f e d c
Type: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [a,b,c,d,e,f])
```

```
p4: P := a*b*c + a*b*f + a*e*f + b*c*d + c*d*e + d*e*f
((c + f)b + f e)a + d c b + e d c + f e d
Type: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [a,b,c,d,e,f])
```

```
p5: P := a*b + a*f + b*c + c*d + d*e + e*f
(b + f)a + c b + d c + e d + f e
Type: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [a,b,c,d,e,f])
```

```
p6: P := a + b + c + d + e + f
a + b + c + d + e + f
Type: NewSparseMultivariatePolynomial(Integer,
```

```

OrderedVariableList [a,b,c,d,e,f])

lp := [p1, p2, p3, p4, p5, p6]
[f e d c b a - 1, (((e + f)d + f e)c + f e d)b + f e d c)a + f e d c b,
(((d + f)c + f e)b + f e d)a + e d c b + f e d c,
((c + f)b + f e)a + d c b + e d c + f e d,
(b + f)a + c b + d c + e d + f e, a + b + c + d + e + f]
Type: List NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [a,b,c,d,e,f])

```

Now call LEXTRIPK.

```

lextripack := LEXTRIPK(R,ls)
LexTriangularPackage(Integer,[a,b,c,d,e,f])
Type: Domain

```

Compute the lexicographical Groebner basis of the system. This may take between 5 minutes and one hour, depending on your machine.

```

lg := groebner(lp)$lextripack
[a + b + c + d + e + f,

```

Note that the first set of the decomposition is normalized (all initials are integer numbers) but not the second one (normalized triangular sets are defined in the description of the `NormalizedTriangularSetCategory` constructor).

So apply now `lexTriangular` to produce normalized triangular sets.

```

```

We check that all initials are constant.

```

[ [init(p) for p in (ts :: List(P))] for ts in lts]
[[1,3,1,3,1,1], [1,1,1,1,1,1], [1,1,1,1,1,1], [1,1,1,1,1,1],
[1387545279120,1387545279120,1387545279120,1387545279120,1387545279120,1],
[1,1,1,1,1,1]]
Type: List List NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [a,b,c,d,e,f])

```

Note that each triangular set in lts is a lexicographical Groebner basis. Recall that a point belongs to the variety associated with lp

if and only if it belongs to that associated with one triangular set  
ts in lts.

By running the squareFreeLexTriangular operation, we retrieve the  
above decomposition.

{f - 1,e + 4f e + f ,d + e + 4f,c - f,b - f,a - f}]
Type: List SquareFreeRegularTriangularSet(Integer,
      IndexedExponents OrderedVariableList [a,b,c,d,e,f],
      OrderedVariableList [a,b,c,d,e,f],
      NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [a,b,c,d,e,f]))

```

Thus the solutions given by lts are pairwise different.

We count them as follows.

```

reduce(+,[degree(ts) for ts in lts])
156
Type: PositiveInteger

```

We can investigate the triangular decomposition lts by using the ZeroDimensionalSolvePackage.

This requires to add an extra variable (smaller than the others) as follows.

```

ls2 : List Symbol := concat(ls,new()$Symbol)
[a,b,c,d,e,f,%A]
Type: List Symbol

```

Then we call the package.

```

zdpack := ZDSOLVE(R,ls,ls2)
(20) ZeroDimensionalSolvePackage(Integer,[a,b,c,d,e,f],[a,b,c,d,e,f,%A])
Type: Domain

```

We compute a univariate representation of the variety associated with the input system as follows.

```

concat [univariateSolve(ts)$zdpack for ts in lts]
